(3) The data for use in (b)(2) above shall be developed by performing additional Charpy V-notch tests on either the welding procedure qualification test heat affected zone or the unaffected base material, or both, at temperatures which provide toughness values that meet or exceed those required for the thickness of the material to be welded in production. The average toughness data for the heat affected zone and unaffected base material shall be plotted on a property temperature chart. The temperature at which these two sets of data exhibit a common acceptable value of toughness for the production thickness involved shall be determined. The determined temperature for the unaffected base material shall be subtracted from the similarly determined temperature for the heat affected zone. This difference, if a positive number, shall be used in (b)(2) above as the adjustment temperature. The welding procedure adjustment temperature shall be added to the highest LST established by the tests of NF-2331 for all of the base material to be welded by this procedure in production. If the temperature difference is zero or a negative number, no adjustment is required for the base material to be welded in production, and the minimum temperature established by the tests for NF-2331 will still apply as stated in (b)(2) above. Where the actual LST is not required for the production material to be welded [for example, where the testing temperature is established by the Design Specification to determine that the material has adequate toughness to meet the toughness requirements of Table NF-2331(a)-1, Table NF-2331(a)-2, Table NF-2331(a)-3, Table NF- 2331(a)-4, Fig. NF-2331(a)-1, or Fig. NF-2331(a)-2 as applicable, at the specified test temperature], the adjustment temperature determined by the curves shall be used to establish a reduction in the specified testing temperature for the production material. The adjustment temperature shall be used to lower the specified testing temperature for any production material on which the procedure will be used.

(c) Should the unaffected base material Charpy V-notch impact test results fail to meet the applicable requirements referenced in (b)(1) above, additional unaffected base material Charpy V-notch impact tests shall be tested at higher temperatures until the applicable requirements are met. Charpy V-notch impact tests of the heat affected zone shall be tested at the same temperature at which acceptable unaffected base material properties were achieved. The rules governing the average toughness of the heat affected zone relative to the average toughness of the unaffected base material shall be followed as in (b)(1) through (3) above to determine the data which are to be recorded on the Welding Procedure Qualification Record.

(d) A Welding Procedure Specification (WPS) qualified to the impact testing requirements of Subsection NB, NC, or NE may be accepted as an alternative to the WPS impact testing requirements of this Subsection.

NF-4400 RULES GOVERNING MAKING, EXAMINING, AND REPAIRING WELDS

NF-4410 PRECAUTIONS TO BE TAKEN BEFORE WELDING

NF-4411 Identification, Storage, and Handling of Welding Materials

Each Certificate Holder is responsible for control of the welding electrodes and other materials which are used in the fabrication and installation of supports (NF-4120). Suitable identification, storage, and handling of electrodes, flux, and other welding material shall be maintained. Precautions shall be taken to minimize absorption of moisture by electrodes and flux.

NF-4412 Cleanliness and Protection of Weld Surfaces

The method used to prepare the base metal shall leave the weld preparation with reasonably smooth surfaces. The surfaces for welding shall be free of scale, rust, oil, grease, and other deleterious material. The work shall be protected from deleterious contamination and from rain, snow, and wind during welding. Welding shall not be performed on wet surfaces.

NF-4420 RULES FOR MAKING WELDED JOINTS

NF-4421 Backing Strips

The materials for backing strips, when used, shall be compatible with the base metal.

NF-4422 Peening

The weld metal may be peened when it is deemed necessary or helpful to control distortion.

NF-4423 Double Welded Joints

Before applying weld metal on the second side to be welded, the root of full penetration double welded joints shall be prepared by suitable methods, such as chipping, grinding, or thermal gouging, except for those processes of welding by which proper fusion and penetration are otherwise obtained and demonstrated to be satisfactory by welding procedure qualification.

NF-4424 Surfaces of Welds

(a) The surface condition of the finished weld shall be sufficiently free from coarse ripples, grooves, overlaps, abrupt ridges, and valleys for the proper interpretation of radiographic and other required nondestructive examinations of the welds. In those cases where there is a question regarding the surface condition on the interpretation of a radiographic film, the film shall be compared to the actual weld surface for interpretation and determination of acceptability.

(b) Concavity on the root side of a single welded circumferential butt weld is permitted when the resulting thickness of the weld meets the requirements of NF-3000.

(c) Fusion shall exist between adjacent layers of weld metal and between weld metal and base metal except as provided in NF-5360(c).

(d) For inertia and continuous drive friction welding, the weld upset shall meet the specified amount within $\pm 10\%$. Flash shall be removed to sound metal.

NF-4427 Shape and Size of Welds

(a) Fillet welds may vary from convex to concave. The shape and size of the weld shall be in accordance with the requirements of Fig. NF-4427-1. Convexity of fillet welds is not a criteria for acceptance and need not be measured.

(b) The faces of groove welds may be flat or convex. The thickness of groove welds shall be no less than $\frac{1}{32}$ in. (0.8 mm) less than the thickness of the thinner of the members joined.

(c) On web-to-flange welds on girders, no underrun as permitted at the ends for a length equal to twice the width of the flange.

NF-4429 Plug Welds

When plug welds are used on supports, a fillet weld shall first be deposited around the circumference at the bottom of the hole.

NF-4430 WELDING OF ATTACHMENTS**NF-4435 Welding of Nonstructural and Temporary Attachments, and Their Removal**

(a) Nonstructural attachments such as insulation supports, nameplates, locating lugs, and temporary attachments may be noncertified material and may be welded to the support or parts thereof with continuous or intermittent fillet or partial penetration welds, provided the requirements of (1) through (5) below are met:

- (1) the welding procedure and the welders have been qualified in accordance with NF-4321;
- (2) the material is identified and is suitable for welding;
- (3) the material is compatible with the material to which it is attached;
- (4) the welding material is identified and compatible with the materials joined;

(5) the welds are postweld heat treated when required by NF-4620.

(b) Removal of temporary attachments shall be accomplished as follows:

- (1) the temporary attachment shall be completely removed in accordance with the procedures of NF-4211;
- (2) as an alternative to (a)(5) above, postweld heat treatment may be deferred until after removal of the attachment;
- (3) the surface of the support shall be visually examined after removal of the temporary attachment.

NF-4440 SPECIAL REQUIREMENTS FOR WELDING

NF-4441 General Requirements

When a primary member of a component support, consists of a plate or a rolled shape and transmits loads in the through thickness direction, one of the following requirements shall be met if the primary member subjected to through thickness loading is 1 in. (25 mm) and greater in thickness.

(a) After completion of welding, the base material directly underneath the attachment shall be ultrasonically examined in accordance with the requirements of NF-5214,

Page 118

NF-5224, or NF-5234, as appropriate to the component support class.

FIG. NF-4427-1 FILLET WELD DIMENSIONS

FIG. NF-4427-1 FILLET WELD DIMENSIONS

(b) A weld metal inlay or overlay shall be made in accordance with Fig. NF-4441-1 and ultrasonically examined in accordance with NF-5214, NF-5224, or NF-5234, prior to making the weld joining the attachment member to the inlay or overlay.

(c) Special deposition techniques, as illustrated in Fig. NF-4441-2, may be used as an alternative to inlay or overlay. Such techniques shall be demonstrated to meet the requirements of (a) above on material thickness equal to or greater than the production thickness but need not be more than 4 in. (102 mm), and on material of the same type and grade as the production material.

(d) The material shall meet the acceptance standards of SA-770, Through-Thickness Tension Testing of Steel Plates for Special Applications.

NF-4450 REPAIR OF WELD METAL DEFECTS

NF-4451 General Requirements

Defects in weld metal detected by the examinations required by NF-5000 shall be eliminated and repaired when necessary.

NF-4452 Elimination of Surface Defects

Weld metal surface defects may be removed by grinding or machining and need not be repaired by welding, provided that the requirements of (a) through (c) below are met.

(a) The remaining thickness of the section is not reduced below that required by NF-3000.

(b) The depression, after defect elimination, is blended uniformly into the surrounding surface.

(c) The area is examined after blending by a magnetic particle or liquid penetrant method in accordance with NF-5110 and meets the acceptance standards of NF-5300 to ensure that the defect has been removed or the indication reduced to an acceptable limit. Defects detected by the visual or volumetric method and located on an interior surface need only be reexamined by the method which initially detected the defect when the interior surface is inaccessible for surface examination.

NF-4453 Requirements for Making Repairs to Welds

Excavations in weld metal, when repaired by welding, shall meet the requirements of the following subparagraphs.

Step 1 Inlay or overlay weldment

Step 2 Completion of weldment

FIG. NF-4441-1 WELD JOINT PRODUCING THROUGH-THICKNESS LOADING

NF-4453.1 Defect Removal.

Defects may be removed by mechanical means or by thermal gouging processes. The area prepared for repair shall be examined by a liquid penetrant or magnetic particle method in accordance with NF-5110 and shall meet the acceptance

GENERAL NOTE: Members may be welded on one side only, or from both sides.

NOTE:

- (1) The initial layer(s) shall extend a minimum of $\frac{3}{8}$ in. beyond the toe of the fillet.

**FIG. NF-4441-2 SPECIAL DEPOSITION TECHNIQUE
FOR WELD JOINT PRODUCING THROUGH-
THICKNESS LOADING (TYPICAL)**

FIG. NF-4441-2 SPECIAL DEPOSITION TECHNIQUE FOR WELD JOINT PRODUCING THROUGH-THICKNESS LOADING (TYPICAL)

THROUGH-THICKNESS LOADING (TYPICAL)

NF-4453.2 Requirements for Welding Materials, Procedures, and Welders.

The weld repair shall be made using welding material, welders, and welding procedures qualified in accordance with NF-4125 and NF-4300.

NF-4453.3 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

NF-4453.4 Examination of Repair Welds.

The examination of a weld repair shall be repeated as required for the original weld, except that it need only be reexamined by the liquid penetrant or magnetic particle method when the unacceptable indication was originally detected by the liquid penetrant or magnetic particle method and when the repair cavity does not exceed the following:

- (a) $\frac{1}{3}t_w$ for $t_w \leq \frac{3}{4}$ in. (19 mm)
- (b) $\frac{1}{4}$ in. (6 mm) for $\frac{3}{4}$ in. (19 mm) $< t_w \leq 2\frac{1}{2}$ in. (64 mm)
- (c) the lesser of $\frac{3}{8}$ in. or 10% t_w for $t_w > 2\frac{1}{2}$ in. (64 mm)

where t_w equals the nominal thickness of the original weld.

NF-4453.5 Heat Treatment of Repaired Areas.

The repaired area shall be heat treated when required by NF-4620.

NF-4500 BRAZING

NF-4510 RULES FOR BRAZING

NF-4511 Where Brazing May Be Used

Furnace brazing is permitted for the construction of supports in accordance with the rules of this Subsection provided the following additional requirements are met.

- (a) Brazing procedures and brazing operators shall be qualified in accordance with Section IX.
- (b) Clearance or interference between mating parts shall be in accordance with the Brazing Procedure Specification.
- (c) Base material shall be limited to material permitted by NF-2120 and Section IX, P-Nos. 101 and 102 ferritic material.
- (d) Brazing alloys shall be limited to Section IX, F-No. 105.
- (e) The allowable shear stress shall be 15.0 ksi or $0.4 \times$ yield strength of base material [NF-3322.1(b)], whichever is less, and the joint shall be loaded principally in shear only.
- (f) Postbrazing heat treatment to develop or restore base material mechanical properties shall be qualified by test specimens which meet the thickness requirements of Section IX, QB-451. The base material test specimens shall be exposed to the same thermal treatment as a brazed part but need not contain a brazed joint. Postbrazing heat treatment of actual parts or test specimens may be performed in the same heat cycle as the brazing operation or in a separate heat cycle. Postbrazing heat treatment shall not exceed 1850°F (1010°C).
- (g) Brazing alloy shall be preplaced on one side of the joint only. Each production joint shall be visually examined after brazing. Brazing metal must be continuous on the preplaced brazing metal side and 85% continuous on the other side.

NF-4512 Brazing Material

Where brazing is permitted, the brazing filler material and fluxes shall conform to the rules covering identification in NF-2150

(a) The filler material used in brazing shall be a nonferrous metal or alloy with a solidus temperature above 800°F (427°C) and at least 500°F (278°C) above the highest temperature of the joint in service.

Page 121

(b) The filler material shall melt and flow freely by capillary action within the desired temperature range, and in conjunction with a suitable flux or controlled atmosphere the filler material shall wet and adhere to the surfaces to be joined.

(c) Fluxes that are fluid and chemically active at the brazing temperature shall be used, when necessary, to prevent oxidation of the filler metal and the surfaces to be joined and to promote free flowing of the filler material.

NF-4600 HEAT TREATMENT

NF-4610 WELDING PREHEAT AND INTERPASS REQUIREMENTS

NF-4611 When Preheat Is Necessary

The need for and temperature of preheat are dependent on a number of factors, such as the chemical analysis, degree of restraint of the parts being joined, elevated temperature, physical properties, and material thicknesses. Some practices used for preheating are given in Appendix D (Section III, Division 1, Appendices) as a general guide for the materials listed by P-Numbers of Section IX. It is cautioned that preheating suggested in Appendix D (Section III, Division 1, Appendices) does not necessarily ensure satisfactory completion of the welded joint and that the preheat requirements for individual materials within the P-Number listing may be more or less restrictive. The Welding Procedure Specification for the material being welded shall specify the minimum preheating requirements under the welding procedure qualification requirements of Section IX.

NF-4612 Preheating Methods

Preheat for welding or thermal cutting, when employed, may be applied by any method which does not harm the base material or any weld metal already applied or which does not introduce deleterious material into the welding area which is harmful to the weld.

NF-4613 Interpass Temperatures

Consideration should be given to limitations of interpass temperatures for quenched and tempered material to avoid detrimental effects on the mechanical properties.

NF-4620 POSTWELD HEAT TREATMENT

NF-4621 Heating and Cooling Methods

Postweld heat treatment (PWHT) may be accomplished by any suitable methods of heating and cooling, provided the required heating and cooling rates, metal temperature, metal temperature uniformity, and temperature control are maintained.

NF-4622 PWHT Time and Temperature Requirements

NF-4622.1 General Requirements.¹

Except as otherwise permitted in NF-4622.7, all welds, including repair welds, shall be postweld heat treated. During postweld heat treatment, the metal temperature shall be maintained within the temperature ranges and for the minimum holding times specified in Table NF-4622.1-1, except as otherwise permitted in NF-4622.4(c). P-Number groups in Table NF-4622.1-1 are in accordance with Section IX, QW-420. Except as provided in NF-4624.3, PWHT shall be performed in temperature-surveyed and -calibrated furnaces, or PWHT shall be performed with thermocouples in contact with the material or attached to blocks in contact with the material. In addition, the requirements of the following subparagraphs shall apply.

NF-4622.2 Time-Temperature Recordings.

Time-temperature recordings of all postweld heat treatments shall be made available for review by the Authorized Inspector. Identification on the time-temperature recording shall be to the weld, part, or support. A summary of the time-temperature recording may be provided for permanent records in accordance with NCA-4134.17.

NF-4622.3 Definition of Nominal Thickness Governing PWHT.

The nominal thickness in Table NF-4622.7(b)-1 is the thickness of the weld, the base material, or the thinner of the base materials being joined, whichever is least. It is not intended that nominal thickness include material provided for forming allowance, thinning, or mill overrun when the excess material does not exceed $\frac{1}{8}$ in. (3.2 mm). For fillet welds, the nominal thickness is the throat thickness and, for partial penetration and material repair welds, the nominal thickness is the depth of the weld groove or preparation.

1 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

Page 122

Page 123

TABLE NF-4622.1-1
MANDATORY REQUIREMENTS FOR POSTWELD HEAT TREATMENT (PWHT) OF WELDS¹

P-Number (Sect. IX, QW-420)	Holding Temperature Range, °F [Note (2)]	Minimum Holding Time at Temperature for Weld Thickness (Nominal)			
		½ in. or Less	Over ½ in. to 2 in.	Over 2 in. to 5 in.	Over 5 in.
1, 3	1100–1250	30 min	1 hr/in.	2 hr plus 15 min each additional inch over 2 in.	2 hr plus 15 min each additional inch over 2 in.
4	1100–1250	30 min	1 hr/in.	1 hr/in.	5 hr plus 15 min each additional inch over 5 in.
5A, 5B, 5C, 6 except P-No. 6 Gr. 4	1250–1400	30 min	1 hr/in.	1 hr/in.	5 hr plus 15 min each additional inch over 5 in.
6 Gr. 4	1100–1150				
7	1300–1400	30 min	1 hr/in.	1 hr/in.	5 hr plus 15 min each additional inch over 5 in.
9A Gr.1	1100–1250	30 min	1 hr/in.	1 hr/in.	5 hr plus 15 min each additional inch over 5 in.
9B Gr. 1	1100–1175				
10A Gr. 1, 10C Gr. 1, 10F Gr. 1	1100–1250	30 min	1 hr/in.	1 hr/in.	5 hr plus 15 min each additional inch over 5 in.
10I Gr. 1	1300–1400				
11A Gr. 1	1025–1085	30 min	1 hr/in.	1 hr/in.	1 hr/in.
11A Gr. 4	1000–1050				
11A Gr. 5	1100–1150				
P-Nos. 8, 10H Gr. 1, 34, 42, 43, 45 and hard sur- facing on P-No. 1 base metal whose reported carbon content is not more than 0.30%	PWHT neither required nor prohibited				

NOTES:

- (1) Exemptions to the mandatory requirements of this Table are defined in NF-4622.7.
(2) All temperatures are metal temperatures.

TABLE NF-4622.1-1 MANDATORY REQUIREMENT FOR POSTWELD HEAT TREATMENT (PWHT) OF WELDS¹

NF-4622.4 Holding Times at Temperature

(a) The holding time at temperature as specified in Table NF-4622.1-1 shall be based on the nominal thickness of the weld. The holding time need not be continuous. It may be an accumulation of the times of multiple postweld heat treatment cycles.

(b) Holding time at temperature in excess of the minimum requirements of Table NF-4622.1-1 may be used, provided that specimens so heat treated are tested in accordance with NF-2200, NF-2400, and NF-4300.

(c) Alternatively, when it is impractical to postweld heat treat at the temperature range specified in Table NF-4622.1-1, it is permissible to perform the postweld heat treatment of certain materials at lower temperatures for longer periods of time in accordance with Table NF-4622.4(c)-1 and (1), (2), and (3) below.

(1) Except for P-No. 1 materials, when welds in the materials listed in Table NF-4622.4(c)-1 are to be postweld heat treated at these lower minimum temperatures, the impact test specimens for the welding procedure qualification required by NF-4300 shall be made using the same minimum temperatures and increased minimum holding time. Welding procedures, qualified at the temperature range and minimum holding time specified in Table NF-4622.1-1 and at the lower minimum temperature and increased minimum holding time permitted by Table NF-4622.4(c)-1, are also qualified for any temperature in between. When such an in-between temperature is used, the minimum holding time shall be interpolated from Table NF-4622.1-1 and the alternative requirements of Table NF-4622.4(c)-1.

(2) Except for P-No. 1 materials, when welds in the materials listed in Table NF-4622.4(c)-1 are to be postweld heat treated at these lower minimum temperatures, the welding material certification required by NF-2400 shall be made using the same minimum temperatures and increased minimum holding time. Welding material certified at the temperature range and minimum holding time specified in Table NF-4622.1-1, and at the lower minimum temperatures and increased minimum holding time permitted by Table NF-4622.4(c)-1 is also certified for any temperature in between.

(3) Base material certified in accordance with NF-2210 may be postweld heat treated at these lower minimum temperatures and increased minimum holding times without recertification. Postweld heat treatment at these lower minimum temperatures and increased minimum holding times may also be the tempering operation, provided a higher tempering temperature is not required by the material specification.

**TABLE NF-4622.4(c)-1
ALTERNATIVE HOLDING TEMPERATURES
AND TIMES¹**

Material P-Numbers	Alternative Minimum Holding Temperatures, °F	Alternative Minimum Holding Times
1, 3, 9A Gr. 1, 9B Gr. 1	1050	2 hr/in. thick
1, 3, 9A Gr. 1, 10A Gr. 1, 9B Gr. 1	1000	4 hr/in. thick

NOTE:

(1) All other requirements of NF-4622 shall apply.

TABLE NF-4622.4(c)-1 ALTERNATIVE HOLDING TEMPERATURES AND TIMES¹

NF-4622.5 PWHT Requirements When Different P-Number Materials Are Joined.

When materials of two different P-Number groups are joined by welding, the applicable postweld heat treatment shall be that specified in Table NF-4622.1-1 for the material requiring the higher PWHT temperature range.

NF-4622.6 PWHT Requirements for Nonpressure-Retaining Parts.

When nonpressure-retaining material is welded to pressure retaining material, the postweld heat treatment temperature range of the pressure retaining material shall control.

NF-4622.7 Exemptions to Mandatory Requirements.

Postweld heat treatment in accordance with this Subarticle is not required for:

(a) nonferrous materials;

(b) welds exempted in Table NF-4622.7(b)-1;

(c) welds subjected to temperatures above the PWHT temperature range specified in Table NF-4622.1-1, provided the Welding Procedure Specification is qualified in accordance with Section IX and the base material and the deposited weld material has been heat treated at the higher temperature;

(d) postweld heat treatment is not required for supports constructed of Type 405 material or of Type 410 material with carbon content not to exceed 0.08%, welded with electrodes that produce an austenitic chromium-nickel weld deposit or a non-air-hardening nickel-chromium-iron weld deposit, provided the plate nominal thickness at the welded joint does

not exceed $\frac{3}{8}$ in. (10 mm), and for thicknesses over $\frac{3}{8}$ in. to $1\frac{1}{2}$ in. (10 mm to 38 mm), provided a preheat of 450°F (232°C) is maintained during welding and the joints are completely radiographed.

NOTES:

(1) The exemptions noted in this Table do not apply to the following:

(a) electron beam welds in ferritic materials over $\frac{1}{8}$ in. in thickness;

(b) inertia and friction welds in material of any thickness of P-No. 3, P-No. 4, P-No. 5, P-No. 7 (except for Types 405 and 410S), P-No. 10, and P-No. 11 materials.

(2) Where the thickness of material is identified in the Type of Weld column, it is the thickness of the base material at the welded joint.

(3) Carbon level of the materials being joined.

TABLE NF-4622.7(b)-1 (CONT'D) EXEMPTION TO MANDATORY PWHT¹**NF-4623 PWHT Heating and Cooling Rate Requirements**

Above 800°F (427°C), the rate of heating and cooling in any hourly interval shall not exceed 400°F (222°C) divided by the maximum thickness in inches of the material being heat treated, but shall not exceed 400°F (222°C) and need not be less than 100°F (56°C) in any hourly interval. During the heating and cooling period there shall not be a greater variation in temperature than 250°F (139°C) within any 15 ft (4.6 m) interval of weld length. The exceptions of (a) and (b) below are permitted.

(a) P-No. 6 material may be cooled in air from the postweld heat treatment holding temperature specified in Table NF-4622.1-1.

(b) For P-No. 7 materials, the cooling rate at temperatures above 1200°F (649°C) shall not exceed 100°F/hr (56°C/hr) after which the rate of cooling shall be sufficiently rapid to prevent embrittlement.

NF-4624 Methods of Postweld Heat Treatment

The postweld heat treatment shall be performed in accordance with the requirements of one of the following subparagraphs.

NF-4624.1 Furnace Heating - One Heat.

Heating the support or item in a closed furnace in one heat is the preferred procedure and should be used whenever practical. The furnace atmosphere shall be controlled so as to avoid excessive oxidation, and direct impingement of flame on the support or item is prohibited.

NF-4624.2 Furnace Heating - More Than One Heat.

The support or item may be heated in more than one heat in a furnace, provided the furnace atmosphere control requirements of NF-4624.1 apply and overlap of the heated sections of the support or item is at least 5 ft (1.5 m). When this procedure is used, the portion of the support or item outside the furnace shall be shielded so that the temperature gradient is

Page 126

not harmful. The cross section where the support or item projects from the furnace shall not intersect a structural discontinuity.

NF-4624.3 Local Heating.

Welds may be locally postweld heat treated when it is not practical to heat treat the entire support or item. Local postweld heat treatment shall consist of heating a circumferential band around the support or item at temperatures within the ranges specified in this Subarticle. The minimum width of the controlled band at each side of the weld, on the face of the greatest weld width, shall be the thickness of the weld or 2 in. (51 mm), whichever is less. The temperature of the support or item from the edge of the controlled band outward shall be gradually diminished so as to avoid harmful thermal gradients. This procedure may also be used for postweld heat treatment after repairs.

NF-4624.4 Internal Heating.

The support or item may be heated internally by any appropriate means and with adequate indicating and recording temperature devices to aid in the control and maintenance of a uniform distribution of temperature in the support or item. Previous to this operation, the support or item should be fully enclosed with insulating material.

NF-4660 HEAT TREATMENT OF ELECTROSLAG WELDS

Electroslag welds in ferritic material over $1\frac{1}{2}$ in. (38 mm) in nominal thickness at the joints shall be given a grain refining heat treatment.

NF-4700 REQUIREMENTS FOR BOLTED CONSTRUCTION

NF-4710 BOLTING AND THREADING

NF-4711 Thread Engagement

The threads of all bolts or studs shall be engaged for the full length of thread in the load carrying nut unless otherwise specified in the Design Documents.

NF-4712 Thread Lubricants

Any lubricant or compound used in threaded joints shall be suitable for the service conditions and shall not react unfavorably with any support element material. Contact surfaces within friction-type joints shall be free of lubricants.

**TABLE NF-4721(a)-1
BOLT HOLE SIZES**

Bolt Size	Hole Size
≤ 1 in.	Bolt diameter plus $\frac{1}{16}$ in.
$1\frac{1}{8}$ in. to 2 in.	Bolt diameter plus $\frac{1}{8}$ in.
> 2 in.	Bolt diameter plus $\frac{3}{16}$ in.

TABLE NF-4721(a)-1 BOLT HOLE SIZES

NF-4713 Removal of Thread Lubricants

All threading lubricants or compounds shall be removed from surfaces which are to be welded.

NF-4720 BOLTING

NF-4721 Bolt Holes

For the purpose of this Article, high strength bolts shall be considered those with specified minimum yield strength greater than 80.0 ksi. Bolt holes shall meet the requirements of (a) through (e) below.

(a) Holes for nonfitted bolts shall meet the requirements of Table NF-4721(a)-1. For anchor bolts set in concrete or concrete expansion anchor, the hole sizes indicated in this Subsection may be increased by $\frac{1}{16}$ in. (1.6 mm). When the bolt hole size is $\frac{1}{8}$ in. (3.2 mm) larger than the bolt, and the bolt is $\frac{1}{2}$ in. (13 mm) or smaller, standard washers shall be used.

(b) Oversized or slotted bolt holes may be used with high strength bolts $\frac{1}{2}$ in. in diameter and larger, except as restricted in (1), (2), and (3) below.

(1) Oversized holes shall not exceed the requirements of Table NF-4721(b)-1. They may be used in any or all plies of friction-type connections. Hardened washers shall be installed over exposed oversized holes.

(2) Short-slotted holes shall not be wider than permitted by (a) above and shall not have a length exceeding the oversize diameter allowed in (1) above by more than $\frac{1}{16}$ in. (1.6 mm). They may be used in any or all plies of friction-type or bearing-type connections. The slots may be used without regard to direction of loading in friction-type connections, but shall be normal to the direction of the load in bearing-type connections. Hardened washers shall be installed over exposed short-slotted holes.

which exceeds $2\frac{1}{2}$ times the bolt diameter. In friction-type connections, the long-slotted holes may be used without regard to direction of loading, provided the stress on the bolts does not exceed 75% of the allowable working stress given in NF-3000. In bearing-type connections, the long diameter of the slot shall be normal to the direction of loading. Long-slotted holes may be used in only one of the connected parts of either a friction-type or bearing-type connection at an individual faying surface. Structural plate washers or a continuous bar not less than $\frac{5}{16}$ in. (8 mm) in thickness shall be used to cover long slots that are in the outer plies of joints. These washers or bars shall have a size sufficient to cover the slot completely after installation and shall meet the requirements of NF-3000.

**TABLE NF-4721(b)-1
TOLERANCES ON OVERSIZED HOLES**

Bolt Size	Hole Size
$\leq \frac{7}{8}$ in.	Bolt diameter plus $\frac{3}{16}$ in.
1 in.	Bolt diameter plus $\frac{1}{4}$ in.
> 1 in.	Bolt diameter plus $\frac{5}{16}$ in.

TABLE NF-4721(b)-1 TOLERANCES ON OVERSIZED HOLES

(c) Except as specified in (d) below, holes may be punched, provided the thickness of the material is not greater than the nominal diameter of the bolt plus $\frac{1}{8}$ in. (3.2 mm). When the thickness of the material is greater than the nominal diameter of the bolt plus $\frac{1}{8}$ in. (3.2 mm), holes shall be drilled, subpunched, and reamed, or thermally cut. Thermal cutting shall not be used unless the load bearing surfaces are machined or ground smooth. For subpunched holes, the die shall be at least $\frac{1}{16}$ in. (1.6 mm) smaller than the nominal diameter of the bolt.

(d) Bolt holes in material over $\frac{1}{2}$ in. (13 mm) thick having a specified minimum yield strength greater than 80.0 ksi (552 MPa) shall be drilled.

(e) For bolts not subjected to shear, the limits for oversized and slotted holes in (d) above may be increased if structural plate washers or continuous bars which meet the requirements of NF-3000 are provided.

NF-4722 Bolted Connections

(a) Surfaces of bolted parts in contact with the bolt head and nut shall not have a slope of more than 1:20 with respect to

a plane normal to the bolt axis. Where the surface of high strength bolted part has a slope of more than 1:20, a beveled washer shall be used to compensate for the lack of parallelism.

(b) Bolts loaded in pure shear shall not have threads located in the load bearing part of the shank unless permitted by the Design Specifications.

NF-4723 Precautions Before Bolting

All parts assembled for bolting shall have contact surfaces free from scale, chips, or other deleterious material. Surfaces and edges to be joined shall be smooth, uniform, and free from fins, tears, cracks, and other defects which would degrade the strength of the joint.

NF-4724 Bolt Tension

All high strength structural bolts shall be preloaded to a value not less than that given in the Design Specifications. Preloading shall be monitored by the turn of nut method, by properly calibrated wrenches, by load indicating washers, or by direct extension indicators. Bolts preloaded by means of a calibrated wrench shall be installed with a hardened washer under the nut or bolt head, whichever is the element turned in preloading. Hardened washers are required under the bolt head and the nut when the direct extension or load indicating washer method is used. Hardened washers are not required when bolts are preloaded by the turn of nut method, except that hardened washers are required under the nut and bolt head when the bolts are used to connect material having a specified yield strength less than 40.0 ksi (276 MPa).

NF-4725 Locking Devices

NF-4725.1 Types of Locking Devices.

Threaded fasteners shall be provided with locking devices to prevent loosening during service. Elastic stop nuts and thread locking compounds (when compatible with service conditions), lock nuts, including full or jam, slotted, drilled and wired, free spinning and prevailing torque are all acceptable locking devices. Upset threads by cold working or tack welding may serve as locking devices. Internally and externally toothed washers, and disk and helical spring lock washers shall not be used as locking devices.

NF-4725.2 Preloading of High Strength Fasteners.

Preloading threaded fasteners made of material with a yield strength of 80 ksi (552 MPa) or greater, loaded

Page 128

in tension, to a value at least 20% above the maximum load on the fastener for the specified loading conditions, limited to 70% of the specified minimum tensile strength of the fastener material satisfies the requirement for locking.

NF-4725.3 Preloading of Non-High Strength Fasteners.

When locking devices cannot be installed because of assembly geometry, preloading of the threaded fasteners in an assembly with fastener material of a yield strength below 80 ksi (552 MPa) is an acceptable method for locking provided the resulting preload is at least 20% above the maximum load on the fastener for the specified loading conditions, but is limited to 70% of the specified minimum tensile strength of the fastener. The threaded assembly shall be tested for the dynamic loading conditions specified in the Design Specification, and the established preload shall be verified on the assembly by properly calibrated wrenches, direct extension indicators, or the turn of the nut method. The results of the test, required preload, and specified thread lubrication shall be provided in the Design Report.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NF-5000

ARTICLE NF-5000 EXAMINATION

Page 129

NF-5100 GENERAL REQUIREMENTS FOR EXAMINATION

NF-5110 PROCEDURES, QUALIFICATIONS, AND EVALUATIONS

NF-5111 General Requirements

Nondestructive examinations shall be conducted in accordance with the examination methods of Section V, except as they may be modified by the requirements of this Article. Radiographic examination shall be in accordance with Section V, Article 2, except that the geometric unsharpness shall not exceed the limits of T-285. Ultrasonic examination shall be in accordance with Section V, Article 5; magnetic particle examination shall be in accordance with Section V, Article 7; liquid penetrant examination shall be in accordance with Section V, Article 6; and visual examination shall be in accordance with Section V, Article 9. The examinations required by this Article or by reference to this Article shall be performed by personnel who have been qualified as required by this Article. The results of the examinations shall be evaluated in accordance with the acceptance standards of this Article.

NF-5112 Nondestructive Examination Procedures

All nondestructive examinations required by this Article shall be performed in accordance with detailed written procedures which have been proven by actual demonstration to the satisfaction of the Inspector. The procedures shall comply with the appropriate Article of Section V for the particular examination method. The digitization of radiographic film and radioscopy images shall meet the requirements of Section V, Article 2, Mandatory Appendix III, "Digital Image Acquisition, Display and Storage for Radiography and Radioscopy." Written procedures and records of demonstration of procedure capability and personnel qualification shall be made available to the Inspector on request. At least one copy of the procedure shall be readily available to all applicable nondestructive examination personnel for reference and use.

NF-5113 Post-Examination Cleaning

Following any nondestructive examination in which examination material is applied to the piece, the piece shall be thoroughly cleaned in accordance with applicable material or procedure specifications.

NF-5114 Rounding-Off of Weld Measurements

In order to properly evaluate specified dimensional sizes, measurements shall be rounded off to the nearest $\frac{1}{32}$ in. (0.8 mm) for undercut and $\frac{1}{16}$ in. (1.6 mm) for weld size. Other dimensions of welds shall be rounded off to the nearest $\frac{1}{8}$ in. (3.2 mm) or as otherwise specified in the design documents.

NF-5120 TIME OF EXAMINATION OF WELDS

Examinations of welds required by NF-5200 shall be performed at the times stipulated in (a) and (b) below during fabrication and installation.

(a) Radiography of welds may be performed prior to any postweld heat treatment.

(b) Magnetic particle or liquid penetrant examination shall be performed after any postweld heat treatment, except that welds in P-No. 1 material may be examined before or after postweld heat treatment.

Page 132

NF-5200 REQUIRED EXAMINATION OF WELDS

NF-5210 EXAMINATION OF CLASS 1 SUPPORT WELDS

NF-5211 Scope

The requirements of this subsubarticle shall apply to all Class 1 supports except that supports for Class 1 piping, NPS2 and less, may be examined by the rules of NF-5220.

NF-5212 Primary Member Welded Joints

- (a) All full penetration butt welded joints in primary members shall be examined by the radiographic method.
- (b) All other welded joints in primary members shall be examined by the liquid penetrant or magnetic particle method, except that the exposed ends of welds need only be visually examined.

NF-5213 Secondary Member Welded Joints

All welded joints in secondary members shall be examined by the visual method.

NF-5214 Special Requirements

For weldments that impose loads in the through thickness direction of primary members 1 in. and greater in thickness, the base material beneath the weld shall be ultrasonically examined, when required by NF-4440, over 100% of the referenced area using the procedure of SA-577 or SA-578, as detailed in Section V to the acceptance standards of NF-5332, except that a calibration block representative of the primary member shall be used. The block for straight beam examination shall have $\frac{1}{4}$ in. (6 mm) diameter flat-bottomed holes at one-fourth, one-half, and three-fourths of the thickness of the member being welded, from which a distance amplitude curve shall be established.

NF-5220 EXAMINATION OF CLASS 2 AND MC SUPPORT WELDS

NF-5221 Primary Member Welded Joints

- (a) All butt welded joints in primary members shall be examined by the liquid penetrant or magnetic particle method.
- (b) All partial penetration or fillet welds in primary members that have a groove depth or throat dimensions greater than 1 in. and T-welded joints welded with throat dimensions of $\frac{1}{2}$ in. or greater shall be examined by the liquid penetrant or magnetic particle method, except that the exposed ends of welds need only be visually examined.
- (c) All primary welds exclusive of those described in (a) and (b) above shall be examined by the visual method.

NF-5222 Secondary Member Welded Joints

All welded joints in secondary members shall be examined by the visual method.

NF-5224 Special Requirements

For weldments that impose loads in the through thickness direction of primary members 1 in. and greater in thickness, the base material beneath the weld shall be ultrasonically examined, when required by NF-4440, over 100% of the referenced area using the procedure of SA-577 or SA-578, as detailed in Section V to the acceptance standards of NF-5332, except that a calibration block representative of the primary member shall be used. The block for straight beam examination shall have $\frac{1}{4}$ in. diameter flat-bottomed holes at one-fourth, one-half, and three-fourths of the thickness of the member being welded, from which a distance amplitude curve shall be established.

NF-5230 EXAMINATION OF CLASS 3 SUPPORT WELDS

NF-5231 Primary Member Welded Joints

- (a) Primary member welded joints that have a groove depth or throat dimension greater than 1 in. shall be examined by the liquid penetrant or magnetic particle method, except that the exposed ends of welds need only be visually examined.
- (b) Primary welded joints exclusive of those described in (a) above shall be examined by the visual method.

NF-5232 Secondary Member Welded Joints

All welded joints in secondary members shall be examined by the visual method.

NF-5234 Special Requirements

For weldments that impose loads in the through thickness direction of primary members 1 in. and greater in thickness, the base material beneath the weld shall

Page 133

be ultrasonically examined, when required by NF-4440, over 100% of the referenced area using the procedure of SA-577 or SA-578, as detailed in Section V to the acceptance standards of NF-5332, except that a calibration block representative of the primary member shall be used. The block for straight beam examination shall have $\frac{1}{4}$ in. (6 mm) diameter flat-bottomed holes at one-fourth, one-half, and three-fourths of the thickness of the member being welded, from which a distance amplitude curve shall be established.

NF-5240 INERTIA AND CONTINUOUS DRIVE FRICTION WELDS

- (a) When radiographic examination is required by this Article, inertia and continuous drive friction welds shall also be examined by the ultrasonic method to verify bonding over the entire area.
- (b) The materials used shall be those assigned a P-Number by Section IX, but shall not include rimmed or semikilled steel.
- (c) One of the two parts to be joined must be held in a fixed position and the other part rotated. The two faces to be joined must be symmetrical with respect to the axis of rotation.
- (d) The weld between the two members shall be a full penetration weld.

NF-5300 ACCEPTANCE STANDARDS

NF-5320 RADIOGRAPHIC ACCEPTANCE STANDARDS

NF-5321 Evaluation of Indications

Indications shown on the radiographs of welds and characterized as imperfections are unacceptable under the following conditions:

- (a) any indication characterized as a crack or zone of incomplete fusion or penetration;
- (b) any other elongated indication which has a length greater than:
 - (1) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive
 - (2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. (19 mm) to $2\frac{1}{4}$ in. (57 mm), inclusive
 - (3) $\frac{3}{4}$ in. for t over $2\frac{1}{4}$ in. (57 mm) where t is the thickness of the thinner portion of the weld;
- (c) internal root weld conditions are acceptable when the density change as indicated in the radiograph is not abrupt; elongated indications on the radiograph at either edge of such conditions shall be unacceptable, as provided in (b) above;
- (d) any group of aligned indications having an aggregate length greater than t in a length of $12t$ unless the minimum distance between successive indications exceeds $6L$, in which case the aggregate length is unlimited, L being the length of the largest indication;
- (e) rounded indications are not a factor in the acceptability of welds that are radiographed.

NF-5330 ULTRASONIC ACCEPTANCE STANDARDS

All imperfections which produce a response greater than 20% of the reference level shall be investigated to the extent that the operator can determine the shape, identity, and location of all such imperfections and evaluate them in terms of the acceptance standards as given in (a) and (b) below.

- (a) Imperfections are unacceptable if the indications exceed the reference level amplitude and have lengths exceeding:
 - (1) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive
 - (2)

3 4 4

(3) $\frac{3}{4}$ in. for t over $2\frac{1}{4}$ in. (57 mm)

where t is the thickness of the weld being examined; if a weld joins two members having different thicknesses at the weld, t is the thinner of these two thicknesses.

(b) Indications characterized as cracks, lack of fusion, or incomplete penetration are unacceptable regardless of length.

NF-5332 Acceptance Standards for Laminar Indications

Any indication detected in the base material beneath the weld which is of a laminar type is unacceptable if the indication cannot be contained within a circle having a diameter equal to one-half of the thickness of the thinner of the members joined.

NF-5340 MAGNETIC PARTICLE ACCEPTANCE STANDARDS

NF-5341 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic

Page 134

permeability variations may produce similar indications which are not relevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. After an indication has been verified to be nonrelevant, it is not necessary to reinvestigate repetitive nonrelevant indications of the same type. Nonrelevant indications which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NF-5342 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

(1) any cracks or linear indications;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm), with the area taken in the most unfavorable location relative to the indications being evaluated.

NF-5350 LIQUID PENETRANT ACCEPTANCE STANDARDS

NF-5351 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities such as may occur from machining marks or surface conditions may produce similar indications which are not relevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NF-5352 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

- (1) any cracks or linear indications;
- (2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);
- (3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;
- (4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimensions of this area not to exceed 6 in. (152 mm), with the area taken in the most unfavorable location relative to the indications being evaluated.

NF-5360 VISUAL ACCEPTANCE STANDARDS

When visual examination is performed in accordance with NF-5200, the acceptance standards shall be in accordance with the following.

(a) Cracks are unacceptable.

(b) A fillet weld is permitted to be less than the size specified by $\frac{1}{16}$ in. (1.6 mm) for one-fourth the length of the weld. Oversized fillet welds are acceptable if the oversized weld does not interfere with mating parts.

(c) In fillet welds, incomplete fusion of $\frac{3}{8}$ in. (10 mm) in any 4 in. (102 mm) segment, and $\frac{1}{4}$ in. (6 mm) in welds less than 4 in. (102 mm) long, is acceptable. For groove welds, incomplete fusion is not acceptable. For fillet and groove welds, rounded end conditions that occur in welding (starts and stops) shall not be considered indications of incomplete fusion and are irrelevant.

(d) Overlap is acceptable provided the criteria for weld size and fusion can be satisfied. When fusion in the overlap length cannot be verified, an overlap length of $\frac{3}{8}$ in. (10 mm) in any 4 in. (102 mm) segment, and $\frac{1}{4}$ in. (6 mm) in welds less than 4 in. (102 mm) long, is acceptable.

Page 135

(e) Craters are acceptable when the criteria for weld size are met. Craters that occur outside the specified weld length are irrelevant provided there are no cracks.

(f) Requirements for acceptability of undercuts are as follows:

(1) For material $\frac{3}{8}$ in. (10 mm) and less nominal thickness, undercut depth of $\frac{1}{32}$ in. (0.8 mm) on one side of the member for the full length of the weld, or $\frac{1}{32}$ in. (0.8 mm) on one side for one-half the length of the weld, and $\frac{1}{16}$ in. (1.6 mm) for one-fourth the length of the weld on the same side of the member is acceptable. For members welded on both sides where undercut exists in the same plane of a member, the cumulative lengths of undercut are limited to the lengths of undercut allowed on one side. Melt-through that results in a hole in the base metal is unacceptable.

(2) For material greater than $\frac{3}{8}$ in. (10 mm) nominal thickness, undercut depth of $\frac{1}{32}$ in. (0.8 mm) for the full length of the weld and $\frac{1}{16}$ in. (1.6 mm) for one-fourth the length of the weld on both sides of the member is acceptable. When either welds or undercut exist only on one side of the member or are not in the same plane, the allowable undercut depth of $\frac{1}{32}$ in. (0.8 mm) may be increased to $\frac{1}{16}$ in. (1.6 mm) for the full length of the weld.

(g) Only surface porosity whose major surface dimension exceeds $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant. Fillet and groove welds that contain surface porosity are unacceptable if:

(1) the sum of diameters of random porosity exceeds $\frac{3}{8}$ in. (10 mm) in any linear inch of weld or $\frac{3}{4}$ in. (19 mm) in any 12 in. (305 mm) of weld; or

(2) four or more pores are aligned and the pores are separated by $\frac{1}{16}$ in. (1.6 mm) or less, edge to edge.

(h) The length and location of welds shall be as specified on the detail drawing, except that weld lengths may be longer than specified. For weld lengths less than 3 in. (76 mm), the permissible underlength is $\frac{1}{8}$ in. (3.2 mm), and for welds 3 in. (76 mm) and longer, the permissible underlength is $\frac{1}{4}$ in. (6 mm). Intermittent welds shall be spaced within 1 in. (25 mm) of the specified location.

(i) Arc strikes and associated blemishes on the weld or in the base material are acceptable provided no cracking is visually detected.

(j) Slag whose major surface dimension is $\frac{1}{8}$ in. (3.2 mm) or less is irrelevant. Isolated surface slag that remains after weld cleaning and does not exceed $\frac{1}{4}$ in. (6 mm) in its major surface dimension is acceptable. [Slag is considered to be isolated when it does not occur more frequently than once per weld or more than once in a 3 in. (76 mm) weld segment.] Spatter remaining after the cleaning operation is acceptable.

NF-5400 ADDITIONAL EXAMINATION REQUIREMENTS FOR STANDARD SUPPORTS

NF-5410 REQUIRED EXAMINATION AND ACCEPTANCE STANDARDS FOR CLASS 1 SPRINGS

Springs for Class 1 variable, constant, and sway standard supports shall be examined after coiling by either the magnetic particle or liquid penetrant method. Linear indications shall be removed by grinding and blending. If the depth of the ground area exceeds 3% of the bar diameter or thickness, the spring shall be rejected.

NF-5420 REQUIRED EXAMINATION AND ACCEPTANCE STANDARDS FOR COILED WIRE ROPE USED AS A SPRING

Coiled wire rope used as a spring shall be visually examined after coiling and shall be free from kinks, loose strands, loose wires, or broken protruding wires.

NF-5500 QUALIFICATIONS AND CERTIFICATION OF NONDESTRUCTIVE EXAMINATION PERSONNEL

NF-5510 GENERAL REQUIREMENTS

Organizations performing Code required nondestructive examinations shall use personnel competent and knowledgeable to the degree specified by NF-5520. When these services are subcontracted by the Certificate Holder or Quality System Certificate Holder, he shall verify the qualification of personnel to the requirements of NF-5520. All nondestructive examinations required by this Subsection shall be performed by and the results evaluated by qualified nondestructive examination personnel.

NF-5520 PERSONNEL QUALIFICATION, CERTIFICATION, AND VERIFICATION

NF-5521 Qualification Procedure

(a) Personnel performing nondestructive examinations shall be qualified in accordance with the recommended

Page 136

guidelines of SNT-TC-1A.¹² The Employer's³ written practice required by paragraph 5 of SNT-TC-1A shall identify Employer requirements relative to the recommended guidelines. The recommended guidelines of SNT-TC-1A shall be considered minimum requirements except as modified in (1) through (5) below.

(1) Qualification of level III nondestructive examination personnel shall be by examination.

(a) The basic and method examinations, paragraphs 8.8(1) and 8.8(2) of SNT-TC-1A, may be prepared and administered by the Employer, ASNT, or an outside agency.

(b) The specific examinations, paragraph 8.8(3) of SNT-TC-1A, shall be prepared and administered by the Employer

or an outside Agency. The employer or outside agency administering the specific examination shall identify the minimum grade requirement in a written program when the basic and method examinations have been administered by ASNT which issues grades on a pass/fail basis. In this case, the minimum grade for the specific examination may not be less than 80%.

(2) The written practice identified in paragraph 5 of SNT-TC-1A and the procedures used for examination of personnel shall be referenced in the Employer's Quality Program.

(3) The number of hours of training and experience for nondestructive examination personnel who perform only one operation of a nondestructive examination method that consists of more than one operation, or perform a nondestructive examination of limited scope, may be less than that recommended in Table 6.3.1 of SNT-TC-1A. The training and experience times shall be described in the written practice and any limitations or restrictions placed on the certification shall be described in the written practice and on the certificate.

(a) The minimum classroom training time identified in Table SNT-TC-1A may be reduced from 8 and 16 hr to 4 and 8 hr, respectively, for visual examination personnel.

1 SNT-TC-1A is a Recommended Practice for Nondestructive Testing Personnel Qualification and Certification published by the American Society for Nondestructive Testing, 1711 Arlingate Lane, P.O. Box 28518, Columbus, Ohio 43228-0518. SNT-TC-1A-1992 is the applicable edition.

2 Personnel qualified by examination and certified to previous editions of SNT-TC-1A are considered to be qualified to the 1992 edition when the recertification is based on continuing satisfactory performance. All reexaminations and new examinations shall be in accordance with the 1992 edition.

3 Employer as used in this Article shall include: N Certificate Holders; Material Organizations' Certificate Holders; Material Organizations who are qualified in accordance with NCA-3862(a)(1); and organizations who provide subcontracted nondestructive examination services to organizations described above.

(4) For visual examination, the Jaeger Number 1 letters shall be used in lieu of the Jaeger Number 2 letters specified in paragraph 8.2(1) of SNT-TC-1A. The use of equivalent type and size letters is permitted.

(5) A Level I individual shall be qualified to perform specific setups, calibrations, and tests, and to record and evaluate data by comparison with specific acceptance criteria defined in written instructions. The Level I individual shall implement these written NDE instructions under the guidance of a Level II or III individual. A Level I individual may independently accept the results of nondestructive examinations when the specific acceptance criteria are defined in the written instructions.

(b) For nondestructive examination methods not covered by SNT-TC-1A documents, personnel shall be qualified to comparable levels of competency by subsection to comparable examinations on the particular method involved.

(c) The emphasis shall be on the individual's ability to perform the nondestructive examination in accordance with the applicable procedure for the intended application.

(d) For nondestructive examination methods that consist of more than one operation or type, it is permissible to use personnel qualified to perform one or more operations. As an example, one person may be used who is qualified to conduct radiographic examination and another may be used who is qualified to interpret and evaluate the radiographic film.

NF-5522 Certification of Personnel

(a) The Employer retains responsibility for the adequacy of the program and is responsible for certification of Level I, II, and III nondestructive examination personnel.

(b) When ASNT is the outside agency administering the Level III basic and method examinations [NF-5521(a)(1)(a)], the Employer may use a letter from ASNT as evidence on which to base the certification.

(c) When an outside agency is the examining agent for Level III qualification of the Employer's personnel, the examination results shall be included with the Employer's record.

NF-5523 Verification of Nondestructive Examination Personnel Certification

The Certificate Holder has the responsibility to verify the qualification and certification of nondestructive examination personnel employed by Material Organizations qualified by them in accordance with NCA 3820,

and subcontractors who provide nondestructive examination services to them.

NF-5530 RECORDS

Personnel qualification records identified in paragraph 9.4 of SNT-TC-1A shall be retained by the Employer.

SEC III D1 NF SI UNITS

SI UNITS

The 1998 Edition of the Boiler and Pressure Vessel Code is based on U.S. Customary (ft-lb) units of measurement which are to be regarded as the standard. This supplement is provided as a convenience to the Code user and contains SI conversion factors for units contained in the Code.

LIST OF SI UNITS FOR USE WITH ASME BOILER AND PRESSURE VESSEL CODE¹

Quantity	Unit	Symbol	Other Units or Limitations
Space and Time			
plane angle	radian	rad	degree (decimalized)
length	meter	m	
area	square meter	m ²	
volume	cubic meter	m ³	liter (L) for liquid only (use without prefix other than in milliliter, mL)
time	second	s	minute (min), hour (h), day (d), week, and year
Periodic and Related Phenomena			
frequency	hertz	Hz	revolutions per second (r/s)
rotational frequency	revolutions per second	s ⁻¹	revolutions per minute (r/m)
Mechanics			
mass	kilogram	kg	
density	kilogram per cubic meter	kg/m ³	
moment of inertia	kilogram · meter ²	kg · m ²	
force	newton	N	
moment of force (torque)	newton-meter	N · m	
pressure and stress	pascal	Pa	(pascal = newton per square meter)
energy, work	joule	J	kilowatt-hour (kW · h)
power	watt	W	
impact strength	joule	J	
section modulus	meter ³	m ³	
moment of section (second moment of area)	meter ⁴	m ⁴	
fracture toughness	Pa · $\sqrt{m}$		
Heat			
temperature — thermodynamic [Note (2)]	kelvin	K	degree Celsius (°C)
temperature — other than thermodynamic	degree Celsius	°C	kelvin (K)
linear expansion coefficient	meter per meter-kelvin	K ⁻¹	°C ⁻¹
quantity of heat	joule	J	
heat flow rate	watt	W	
thermal conductivity	watt per meter-kelvin	W/(m · K)	W/(m · °C)
thermal diffusivity	square meter per second	m ² /s	
specific heat capacity	joule per kilogram-kelvin	J/(kg · K)	J/(kg · °C)
Electricity and Magnetism			
electric current	ampere	A	
electric potential	volt	V	
current density	ampere per meter ²	A/m ²	
magnetic field strength	ampere per meter	A/m	

NOTES:

- (1) Conversion factors between SI units and U.S. customary are given in SI-1, "ASME Orientation and Guide for Use of SI (Metric) Units," and ASTM E 380.
- (2) Preferred use for temperature and temperature interval is degrees Celsius (°C), except for thermodynamic and cryogenic work where kelvins may be more suitable. For temperature interval, 1 K = 1°C exactly.

NOTES:

- (1) Care should be taken when converting formulas or equations that contain constant terms or factors. The value of these terms must be understood and may also require conversion.
- (2)(a) Relationships that are exact in terms of the base units are followed by a single asterisk.
 (b) The factors are written as a number greater than 1 and less than 10 with 6 or less decimal places. The number is followed by the letter E (for exponent), a plus or minus symbol, and two digits which indicate the power of 10 by which the number must be multiplied to obtain the correct value. For example: 3.523 907 E-02 is $3.523\ 907 \times 10^{-2}$ or 0.035 239 07.

APPENDIX NF-II DESIGN OF SINGLE ANGLE MEMBERS

Page 147

Page 149

ARTICLE NF-II-1000 INTRODUCTION

NF-II-1100 SCOPE

This Mandatory Appendix provides design rules for single angle members that are used in Section III, Division 1 Class 1, 2, 3, and MC linear component support construction.

NF-II-1200 GENERAL REQUIREMENTS

The requirements of Article NF-3000 shall be met except as modified by this Appendix.

Page 150

ARTICLE NF-II-2000 NOMENCLATURE

Nomenclature is given in NF-3313 except as noted in NF-II-3200 to NF-II-3600.

Page 151

ARTICLE NF-II-3000 DESIGN REQUIREMENTS

NF-II-3100 GENERAL

Single angle members are designed in accordance with NF-II-3200 to NF-II-3600.

NF-II-3200 TENSION

The allowable tension stress F_t shall not exceed $0.6S_y$ on the gross area A_g , nor $0.50S_u$ on the effective net area A_e .

(a) For members connected by bolting, the net area and effective net area shall be determined from NF-3322.8

(b) When the load is transmitted by longitudinal or combination of longitudinal and transverse welds through just one leg of the angle, the effective net area shall be:

$$(1) A_e = 0.85 A_g$$

(c) When the load is transmitted by transverse weld through just one leg of the angle, A_e is the area of the connected leg.

NF-II-3300 SHEAR

The allowable shear stress due to flexure and torsion shall be:

$$(2) F_v = 0.4S_y$$

NF-II-3400 COMPRESSION

The allowable compressive stress on the gross area of axially compressed members shall be:

when $Kl/r < C_c$

$$F_a = \frac{Q \left[1 - \frac{(Kl/r)^2}{2C_c'^2} \right] S_y}{5/3 + 3/8 \left(\frac{Kl/r}{C_c'} \right) - \frac{(Kl/r)^3}{8C_c'^3}} \quad (3)$$

(3)

when $Kl/R > C_c$

$$F_a = \frac{12 \pi^2 E}{23 (Kl/r)^2} \quad (4)$$

(4)

where

Kl/r

= largest effective slenderness ratio of any unbraced length as defined in NF-3322.2

$$C'_c = \sqrt{\frac{2 \pi^2 E}{Q S_y}}$$

The reduction factor Q shall be:

when $b/t \leq 76/\sqrt{S_y}$

$$(5) Q = 1$$

when $76/\sqrt{S_y} < b/t < 155/\sqrt{S_y}$

$$(6) Q = 1.340 - 0.00447 (b/t) \sqrt{S_y}$$

when $b/t \geq 155/\sqrt{S_y}$

$$(7) Q = 15,500/[S_y(b/t)^2]$$

where

b = full width of the longest angle leg

t = thickness of angle

For short, thin, or unequal leg angles, flexural-torsional buckling may produce a significant reduction in strength.

Page 152

In such cases, the allowable stress shall be determined by the previous equations substituting an equivalent slenderness ratio $(Kl/r)_{\text{equiv}}$ for Kl/r

$$(Kl/r)_{\text{equiv}} = \pi \sqrt{E/F_e}$$

where F_e is the elastic buckling strength for the flexural-torsional mode.

(a) For equal leg angles with w as the axis of symmetry:

$$F_e = \frac{F_{ew} + F_{ej}}{2H} \left[1 - \sqrt{1 - \frac{4 F_{ew} F_{ej} H}{(F_{ew} + F_{ej})^2}} \right]$$

(b) For unequal leg angles, F_e is the lowest root of the cubic equation:

$$(F_e - F_{ez})(F_e - F_{ew})(F_e - F_{ej}) - F_e^2(F_e - F_{ew})(z_o/\bar{r}_o)^2 - F_e^2(F_e - F_{ez})(w_o/\bar{r}_o)^2 = 0$$

where

E	= modulus of elasticity, ksi
G	= shear modulus, ksi
J	= torsional constant = $2bt^3/3 = t^3A/3$, in. ⁴
I_z, I_w	= moment of inertia about <i>principal</i> axes, in. ⁴
z_o, w_o	= coordinates of the shear center with respect to the centroid, in.

$$\bar{r}_o^2 = z_o^2 + w_o^2 + (I_z + I_w)/A, \text{ in.}^2; \quad I_z + I_w = I_x + I_y$$

$$H = 1 - (z_o^2 + w_o^2)/\bar{r}_o^2 = (I_z + I_w)/A\bar{r}_o^2$$

A	= cross-sectional area, in. ²
l	= unbraced length, in.
K_z, K_w	= effective length factors
r_z, r_w	= radii of gyration about principal axes

For members whose design is based on compressive force, the largest effective slenderness ratio preferably should not exceed 200.

NF-II-3500 FLEXURE

The allowable bending stress limits of NF-II-3510 shall be used as indicated in NF-II-3520 and NF-II-3530.

NF-II-3510 ALLOWABLE BENDING STRESS

The allowable bending stress, F_b , is a function of the unbraced length to width ratio (l/b) and the width to thickness ratio (b/t) of the single angle member.

For equal leg angles fabricated from materials with a minimum specified yield strength of 36 ksi and 50 ksi, Fig. NF-II-3510 may be used to determine the limiting combination of l/b and b/t for which F_b is equal to $0.66S_y$. For equal leg angles not meeting the limits of Fig. NF-II-3510 and for unequal leg angles, the bending stress is limited to the minimum allowable value F_b determined from NF-II-3511, NF-II-3512, and NF-II-3513 as applicable.

NF-II-3511

To prevent local buckling when the tip of an angle leg is in compression.

when $b/t \leq 65/\sqrt{S_y}$:

$$(8) F_b = 0.66S_y$$

when $65/\sqrt{S_y} < b/t \leq 76/\sqrt{S_y}$:

$$(9) F_b = 0.60S_y$$

when $b/t > 76/\sqrt{S_y}$:

$$(10) F_b = 0.60Q S_y$$

where

b = full width of angle leg in compression

Q = stress reduction factor per Eqs. (5), (6), and (7) with b as defined above

An angle leg shall be considered to be in compression if the tip of the angle leg is in compression, in which case the calculated stress f_b at the tip of this leg is used.

NF-II-3512

For the tip of an angle leg in tension

$$(11) F_b = 0.66S_y$$

FIG. NF-II-3510 EQUAL LEG SINGLE ANGLE LIMITS FOR $F_b = 0.66S_y$
(Reprinted with Permission of AISC)

FIG. NF-II-3510 EQUAL LEG SINGLE ANGLE LIMITS FOR $F_b = 0.66S_y$

NF-II-3513

To prevent lateral-torsional buckling, the maximum compression stress shall not exceed:

when $F_{ob} \leq S_y$

$$(12) F_b = [0.55 - 0.10 F_{ob}/S_y] F_{ob}$$

when $F_{ob} > S_y$

$$(13) F_b = [0.95 - 0.50 \sqrt{S_y/F_{ob}}] S_y \leq 0.66S_y$$

where

F_b

= allowable bending stress at leg tip, ksi

F_{ob}

= elastic lateral-torsional buckling stress, from NF-II-3520 or NF-II-3530 as applicable, ksi

S_y

= yield stress, ksi

NF-II-3520 BENDING ABOUT GEOMETRIC AXES

NF-II-3521

(a) Angle bending members with lateral-torsion restraint along the length may be designed on the basis of geometric axis bending with stress limited by the provisions of NF-II-3511 and NF-II-3512.

(b) For equal leg angles if the lateral-torsional restraint is only at the point of maximum moment, the stress f_b is calculated on the basis of geometric axis bending limited by F_b in NF-II-3522.

NF-II-3522

Equal leg angle members without lateral-torsional restraint subjected to flexure applied about one of the geometric axes may be designed considering only geometric axis bending provided:

(a) The calculated compressive stress f_b using the geometric axis section modulus, is increased by 25%.

(b) For the angle leg tips in compression, the allowable bending stress F_b is determined according to NF-II-3513, where

$$F_{ob} = \frac{85,900}{(l/b)^2} C_b \left[\sqrt{1 + 0.78 (lt/b^2)^2} - 1 \right] \quad (14)$$

(14)

Page 154

and by b/t provisions in NF-II-3511. When the leg tips are in tension, F_b is determined only by NF-II-3512.

l = unbraced length, in.

C_b = $1.75 + 1.05(M_1/M_2) + 0.3(M_1/M_2)^2 \leq 1.5$, where M_1 is the smaller and M_2 the larger end moment in the unbraced segment of the beam; (M_1/M_2) is positive when the moments cause reverse curvature and negative when bent in single curvature. C_b shall be taken as unity when the bending moment at any point within an unbraced length is larger than at both ends of its length.

NF-II-3523

Unequal leg angle members without lateral-torsional restraint subjected to bending about one of the geometric axes shall be designed using NF-II-3530.

NF-II-3530 BENDING ABOUT PRINCIPAL AXES

Angles without lateral-torsional restraint shall be designed considering principal axis bending except for cases covered by NF-II-3522. Bending about both of the principal axes shall be evaluated using the interaction equations in NF-3322.1

(e)(1).

NF-II-3531 Equal Leg Angles

(a) *Major Axis Bending.* The principal bending compression stress f_{bw} shall be limited by F_b in NF-II-3513, where

$$F_{ob} = C_b \frac{28,250}{(l/t)} \quad (15)$$

(15) and by b/t provisions in NF-II-3511.

(b) *Minor Axis Bending.* The principal bending stress f_{bz} shall be limited by F_b in NF-II-3511 when the leg tips are in compression, and by NF-II-3512 when the leg tips are in tension.

[98]

NF-II-3532 Unequal Leg Angles

(a) *Major Axis Bending.* The principal bending compression stress f_{bw} shall be limited by F_b in NF-II-3513, where

$$F_{ob} = \frac{143,100 I_z}{S_w l^2} C_b \left[\sqrt{B_w^2 + 0.052 (lt/r_z)^2} + B_w \right] \quad (16)$$

(16) and by b/t provisions in NF-II-3511 for the compression leg.

S_w	= section modulus to tip of leg in compression, in. ³
I_z	= minor principal axis moment of inertia, in. ⁴
r_z	= radius of gyration for minor principal axis, in.

$$B_w = \left[\frac{1}{I_w} \int_A z (w^2 + z^2) dA \right] - 2z_o$$

= special section property for unequal leg angles, positive for short leg in compression and negative for long leg in compression, in. Table NF-II-3532-1 lists some values for standard angles. If the long leg is in compression anywhere along the unbraced length of the member, use the negative value of B_w .

z_o

= coordinate along z axis of the shear center with respect to centroid, in.

I_w

= major principal axis moment of inertia, in.⁴

TABLE NF-II-3532-1
 B_w VALUES FOR ANGLES

Angle Size, in.	B_w , in.
9 × 4	6.54
8 × 6	3.31
8 × 4	5.48
7 × 4	4.37
6 × 4	3.14
6 × 3.5	3.69
5 × 3.5	2.40
5 × 3	2.99
4 × 3.5	0.87
4 × 3	1.65
3.5 × 3	0.87
3.5 × 2.5	1.62
3 × 2.5	0.86
3 × 2	1.56
2.5 × 2	0.85
Equal legs	0.00

TABLE NF-II-3532-1 B_w VALUES FOR ANGLES

(b) *Minor Axis Bending.* The principal bending stress f_{bz} shall be limited by F_b in NF-II-3511 when leg tips are in compression and by NF-II-3512 when the leg tips are in tension.

[98]

NF-II-3600 COMBINED STRESSES

NF-II-3610 AXIAL COMPRESSION AND FLEXURE

Members subjected to both axial compression and bending shall satisfy the requirements of NF-3322.1(e)(1).

Page 155

NF-II-3611

In evaluating Eqs. (20) or (22) of NF-3322.1(e)(1) the maximum compression bending stresses due to each moment acting alone must be used even though they may occur at different cross sections of the member.

NF-II-3612

Equation (21) of NF-3322.1(e)(1) is to be evaluated at the critical member support cross section and need not be based on the maximum moments along the member length.

NF-II-3613

For members constrained to bend about a geometric axis with compressive stress and allowable stress determined per NF-II-3521(a), the radius of gyration r_b for F_e' shall be taken as the geometric axis value.

NF-II-3614

For equal leg angles without lateral-torsional restraint along the length and with bending applied about one of the geometric axes, the provisions of NF-II-3522 shall apply for the calculated and allowable bending stresses. If NF-II-3521 (b) or NF-II-3522 is used for F_b , the radius of gyration about the axis of bending r_b for F_e' shall be taken as the geometric axis value of r divided by 1.35 in the absence of a more detailed analysis.

NF-II-3615

For members that do not meet the conditions of NF-II-3613 or NF-II-3614, the evaluation shall be based on principal axis bending according to NF-II-3530, and the subscripts x and y in NF-3322.1(e)(1) shall be interpreted as the principal axes, w and z , in this Appendix when evaluating the length without lateral-torsional restraint.

NF-II-3620 AXIAL TENSION AND BENDING

Members subjected to both axial tension and bending stresses due to transverse loading shall satisfy the requirements of Eq. (22) of NF-3322.1(e)(1). Bending stress evaluation shall be as directed by NF-II-3613, NF-II-3614, and NF-II-3615 for compressive stresses.

APPENDIX NF-III ENERGY ABSORBING SUPPORT MATERIAL

Page 157

[98]

ARTICLE NF-III-1000 GENERAL REQUIREMENTS

Energy absorbing material of linear-type pipe supports designed to Subsection NF which is designed to dissipate energy associated with dynamic piping movements by yielding, shall be constructed for services in accordance with Section III, Division 1, Subsection NF, as modified by this Appendix.

[98]

Page 160

[98]

ARTICLE NF-III-2000 MATERIAL REQUIREMENTS

(a) When plate material is used, it shall not exceed 1 in. nominal thickness.

(b) Weld repairs of energy absorbing materials shall not be permitted.

(c) In lieu of NF-2311(a)(3), impact testing shall be in accordance with NF-2300. For SA-516 material, impact testing shall be required when the nominal section thickness exceed $\frac{5}{8}$ in. and the lowest service temperature is less than the values listed below:

Class	Normalized	As Rolled
Class 1, 2, and MC	30°F	70°F
Class 3	0°F	50°F

(d) All other requirements of NF-2000 shall apply.

[98]

Page 161

[98]

ARTICLE NF-III-3000 DESIGN

For the design of energy absorbing support material that perform by sustaining strains beyond elastic limits, the following rules shall apply in lieu of those in NF-3140 and NF-3300.

(a) *Fatigue Design*

(1) Energy absorbing support material may be designed by load rating. The load rating of these parts shall provide for a relationship between imposed strains and the allowable number of cycles.

(2) Cumulative fatigue effects associated with all strain cycles expected for the life of the energy absorbing support parts resulting from all service loadings shall be evaluated as follows:

$$\sum \frac{n_{ti}}{N_{ti}} + \sum \frac{n_{dj}}{N_{dj}} \leq 1$$

where

n_{dj}	= expected number of cycles associated with dynamic load, j
n_{ti}	= expected number of cycles associated with the supported piping system in going from one service temperature to another, i
N_{dj}	= allowable number of cycles read from the design fatigue curve, as defined below, corresponding to the amplitude of the strain induced by the dynamic load, j
N_{ti}	= allowable number of cycles read from the design fatigue curve, as defined below, corresponding to the amplitude of the strain induced by the dynamic load, i

(b) *Design Fatigue Curves.* Design fatigue curves based on testing of prototypical samples of energy absorbers shall be developed and used in the fatigue design. Samples tested shall represent the material used for construction, shapes used, and methods of fabrication. The fatigue design curves shall show a relationship between the amplitude of strain (ϵ) and the allowable number of cycles (N). The ordinate shall show the value of strain, ϵ , and the abscissa shall show the allowable number of cycles, N , calculated as follows:

$$N_{\text{mean}}/1.5 \text{ or } (N_{\text{mean}} - \sigma \times 2)$$

whichever is smaller, where

N_{mean}	= mean number of cycles to failure of specimen tested at strain value, ϵ
σ	= maximum deviation

(c) *Dead Weight Consideration.* Loads induced by the dead weight effect of a supported piping system should not exceed one-fifth of the elastic yield load capacity of the energy absorbing supports. The elastic yield load shall be based on the yield strength given in Appendix I (Section III, Division 1, Appendices) for the material of the energy absorbing parts.

(d) *Steady State Vibration Consideration.* Operational steady state vibration effects on the energy absorbing support parts, if present, shall be maintained within the endurance limit from the applicable fatigue design curves of Appendix I (Section III, Division 1, Appendices).

(e) *Piping Design Consideration.* The inelastic characteristics of energy absorbing support parts shall be considered in satisfying all design and service loadings for which the supported piping is evaluated.

[98]

Page 162

[98]

ARTICLE NF-III-4000 FABRICATION

(a) Welding shall not be permitted for fabrication and installation of energy absorbing support material.

(b) All other requirements of NF-4000 shall apply.

APPENDIX NF-A STRUCTURAL BOLT PRELOADING

NONMANDATORY

APPENDICES

Page 165

ARTICLE NF-A-1000 INTRODUCTION

NF-A-1100 SCOPE

This Appendix provides general guidance on structural bolt preloading of steel to steel joints. AISC specifications should be followed when using A490 or A325 bolts. For other bolting materials, detailed specifications are not generally available and the following discussion is to be used in understanding the importance of proper tightening, and to help select a reliable method to be employed where detailed specifications are not available.

NF-A-1200 DISCUSSION

The American Institute of Steel Construction (AISC) provides a rather detailed specification when using A490 or A325 bolts. The AISC specification provides guidance with regard to:

- (a) bolt and nut specification;
- (b) washers;
- (c) faying surface coatings;
- (d) surface conditions;
- (e) hole types and tolerances;
- (f) allowable strengths and working stresses;
- (g) bearing force;
- (h) prying action;
- (i) tensile fatigue;

- (j) definition of "slip critical" joints;
- (k) allowable slip load; and
- (l) reuse of bolts.

It provides guidance for installation and tightening including: discussion of what is required for a tension calibrator; joint assembly for bearing loading; joint assembly for joints requiring full pretensioning; turn-of-the-nut tightening; and calibrated torque wrench tightening.

It should be noted that AISC (Ninth Edition) does not recommend use of torque wrenches as the preferred method of bolt tightening. Rather, it recommends turn-of-the-nut over the torque wrench method. This is true because of the variations in tension that are expected due to the many variables that are present in tensioning by use of a torque wrench. For "turn-of-the-nut" it provides a table for required turns for various diameters and squareness conditions of the bolted parts.

AISC also requires that torque wrenches are calibrated every day that they are used.

The following clarifies why such large variations are expected from bolt tensioning by use of a torque wrench.

The major consideration in any fastening problem is to determine as accurately as possible the best kind of fastener which, when properly tightened, will ensure engineering reliability of the end product. Reliability of threaded fasteners that will be subjected to cyclic/vibratory loads is based largely on the torque-tension relationship in which tension (preload as it is commonly called), not torque, is the most critical measurement.

Preload induced in a fastener is best set within an optimum range which is determined from maximum and minimum values of the variable joint loading. Too little preload will allow stress fluctuations in the joint which lead to fatigue failure. Too much preload may cause fracture or plastic elongation with resulting loss of clamping force.

Several methods are available for measuring preload. These are listed below with cost and anticipated accuracy.

Preload Measuring Method	Accuracy (%)	Relative Cost
Feel (operator's judgement)	±35	1
Torque wrench	±25	1½
Turn-of-the-nut	±15	3
Load-indicating washers	±10	7
Fastener elongation	±3 to 5	15
Strain gauges	±1	20

(REF: Industrial Fastener Institute.)

Improved accuracy incurs higher cost in assembly, for example, the use of strain gages would be approximately

20 times more expensive than merely relying upon the judgment and feel of the operator.

Each method possesses certain advantages and disadvantages with ultimate choice based on a compromise of application requirements.

NF-A-1300 BOLT TIGHTENING (PRELOAD METHODS)

NF-A-1310 TORQUE WRENCHES

The use of torque wrenches is the most popular method of preload measurement because of simplicity. Because of the many interrelated variables that directly or indirectly affect friction, such as: surface texture, type of coating or finish, amount of lubrication, speed of tightening, etc., it is possible to experience as much as ±25% variation in preload between similar fasteners receiving identical torques. Closer control of torque wrench calibration can reduce deviation to ±15%.

In all cases, hardened washers should be used beneath the bolt head or nut (whichever is rotated during tightening) when tightening by torque wrench method.

NF-A-1311 Empirical Equations for Tension From Bolt Torque

The following empirical equation is often used to provide an "estimate" of the torque required to induce a given preload in a bolt:

$$(1) T = KDW$$

where

T	= torque, lb-in.
K	= torque coefficient (not to be confused with coefficient of friction)
D	= nominal bolt size, in.
W	= bolt tension, lb

The torque coefficient K is the critical parameter in the above formula and can be calculated by various methods, all of which represent approximations at best. It is primarily influenced by the frictional conditions along the thread flank and at the bearing surfaces. Relative resiliency of the fastener and joint material also provide influence. For these reasons, it is best to experimentally determine K for critical applications using actual joint material and assembly tools. Arbitrary values for K are often assigned in noncritical applications as follows:

K	= 0.20 for nonplated steel fasteners ¹
K	= 0.15 for plated fasteners ¹

FIG. NF-A-1311

FIG. NF-A-1311

Generally, the above K values are conservative, and the actual preload induced by a given torque is slightly less than calculated.

A more exact value of K is expressed by the following equation, provided there is no thread interference such as by a locknut or wrench-tight thread fit:

$$K = U_B \frac{R_B}{D} + \frac{R_T}{D} \left(\frac{U_T \sec \beta + \tan C}{1 - U_T \sec \beta \tan C} \right) \quad (2)$$

(2)

where

U_B	= coefficient of friction at bearing face of nut or bolt
U_T	= coefficient of friction at thread contact surfaces
R_B	= effective radius of action of frictional forces on bearing face, in. (See Fig. NF-A-1311)
R_T	= effective radius of action of frictional forces on thread surfaces, in.
β	= thread half-angle (30 deg. for 60 deg. basic thread form; sec $\beta = 1.15$)
C	= helix angle of thread

1 In applications where additional lubricants such as greases, oils, and waxes are applied to the fasteners, K may be assumed to be as low as 0.12.

For threads used for fasteners, the denominator of the bracketed term is unity within $\pm 1/2\%$, so

$$\begin{aligned}
 K &= U_B \frac{R_B}{D} + U_T \frac{R_T}{D} \sec \beta + \frac{R_T}{D} \tan C \\
 &= K_1 + K_2 + K_3
 \end{aligned} \tag{3}$$

(3)

The approximate values of K_1 , K_2 , and K_3 can be calculated by inserting typical values such as $R_B/D = 0.625$; $U_B = U_T = 0.15$; $R_T/D = 0.45$; $\sec \beta = 1.15$; $\tan C = 0.04$.

$$K = 0.094 + 0.078 + 0.018 = 0.190$$

$$\frac{100K}{0.190} = 49.5\% + 41\% + 9.5\% = 100\%$$

So, it is observed that K_1 , K_2 , and K_3 contribute roughly 50%, 40%, and 10%, respectively, to the torque coefficient K .

Coefficient K_1 represents the torque resulting from friction on the bearing face of the nut or bolt. This is about 50% of the total torque. K_1 varies with the coefficient of bearing face friction (0.12-0.20) and also with the effective radius of the bearing face, R_B . The radius R_B is approximately the average radius of the bearing face if the contact pressure is uniform.

(NOTE: The exact theoretical values of R_B for uniform contact pressure is

$$R_B = \frac{2}{3} \left(\frac{R_o^3 - R_i^3}{R_o^2 - R_i^2} \right)$$

where R_o and R_i are the outer and inner bearing radii, respectively.)

If the bearing face is not true and flat and the pressure uniform, R_B may vary from the inner radius of the bearing face to the outer radius.

Coefficient K_2 represents the torque resulting from friction on the contact flanks of the threads. This represents about 40% of the total torque. K_2 varies with the coefficient of thread friction (0.12-0.20) and also with the radius of action of friction on thread faces, R_T . The radius R_T is approximately the pitch radius of the screw thread if thread contact pressure is uniform. If contact pressure is not uniform, R_T may vary from the inner to the outer radius of contact of threads. The radius R_T also will differ between coarse and fine threads, being larger for fine threads, resulting in higher torque. K_2 is also slightly variable with bolt tension because of increase in angle β due to thread bending under load. The increase in angle may be considerable at loads near thread failure by stripping.

Coefficient K_3 represents the useful torque producing bolt tension. This is about 10% of the total applied torque. K_3 varies with R_T (see K_2 above) and with the helix angle of the thread. The helix angle, C , varies with the bolt size, being somewhat larger for smaller bolt sizes. It also varies between coarse and fine threads, being slightly larger for coarse threads.

NF-A-1312 Summary of Tensioning by Torque

From the preceding discussion, the following summary can be made:

(a) Equation (1), using $K = 0.2$, gives a reasonable estimate of torque required to produce a given tension regardless of bolt size or thread pitch. This applies only to washer faced or double chamfered hex nuts (or bolts if bolt is torqued) having a width across flats of about 1.5 times the nominal diameter; to threads free of interference such as provided by a locknut or wrench-tight thread fit; to steel bolts and nuts as normally produced and without added plating or lubrication; and to applications where the torqued bearing face of the fastener is in contact with relatively smooth, unplated, nonlubricated steel surfaces.

(b) A more exact theoretical expression of K can be obtained from Equation (3).

(c) There is considerable variation in the value of K from bolt to bolt even when conditions are well controlled because of variation in coefficient of friction. Therefore, where closer control of tension is required, the value of K should be determined experimentally for the particular application. Even so, K will vary considerably because of variations in field conditions.

(d) There is little difference in K between coarse and fine threads - the value for coarse threads being only about $2\frac{1}{2}\%$ higher than that for fine threads, which is negligible. This may be surprising to some people who may think that the small helix angle of fine threads should produce tension with considerably less torque. Such is not the case, however, because 90% of the torque effort is consumed by friction regardless of the thread pitch. This high frictional effect also helps prevent loosening of the fastener.

(e) The value of K as estimated does not apply at or near the failure point of the bolt-nut combination, particularly if the imminent failure is by stripping of threads. In this situation, there may be galling of contact surfaces with greatly increased K . Also, the thread angle, β , becomes greatly distorted, further increasing K . These influences, added to the normal variations of K , result in an indeterminate value of K . From this, it is evident that the torque at failure cannot be taken as any reliable measure of the strength of the fastener.

NF-A-1320 TURN-OF-THE-NUT

Turn-of-the-nut tightening process encompasses a low initial "threshold" torque to achieve "snug tight" condition (achieved by a few impacts of an impact wrench or the force of a person using a spud wrench) followed by a prescribed amount of nut turning to develop the required preload. This technique has gained acceptance for installation of high strength structural bolts, and can be reliably extrapolated to smaller fasteners as long as assumptions upon which the technique is based are considered. For example, the ideal snug-tight condition will vary with each application.

Nut rotation through a prescribed amount eliminates the influence of all friction variables relative to final accuracies. Also, a one-half turn from snug-tight of a coarse thread nut on a bolt having a grip length (the clamping distance between the bolt head and nut) less than 8 in. will induce preload equal to or slightly over the bolt's rated proof load. For grip lengths greater than 8 in., two thirds of a turn beyond snug-tight is recommended.

NF-A-1330 LOAD-INDICATING WASHERS

Load-indicating washers provide high reliability for initial indication of fastener tension. The load-indicating washer employs small raised areas on a ductile washer face that will deform under compression at the time of tightening. A feeler gage is employed to measure the amount of deformation to supply the correct fastener tension. Although these devices are accurate within 10% of expected tension, they cannot be reused if the bolted joint is disassembled for any reason. In addition, if the preload relaxes over time, there is no way to check the bolt tension short of installing new load-indicating washers.

Presence or lack of lubrication during installation does not have an adverse effect on the ability of the load-indicating washer to measure the correct tension in the assembly. In general this simple method of measuring tension can be considered a reliable, fairly economical way to correctly tension bolted assemblies.

NF-A-1340 STRAIN GAGES

Strain gages provide high accuracy in measuring bolt tension, but are also, by far, the most expensive way of accomplishing this task.

The strain gage is a small electrical device with a foil or wire element that is mechanically bonded to the bolt shank. When the bolt is tightened the strain gage experiences the same elongation as the bolt shank. When the foil or wire element is subjected to this strain, its cross sectional area changes slightly causing its electrical resistance to change. Using sensitive equipment, a direct relationship between resistance change and strain can be determined.

Application of strain gage technology requires highly qualified personnel, careful care in application of the gages, and careful calibration of equipment. Other variables that can affect accurate strain gage readings are: the orientation (alignment) of the strain gage element; temperature effects. If out of squareness in the bolt heads or surfaces exists, bolt bending will occur, and this will give an incorrect indication of actual bolt tension. Strain gages installed 180 deg. to each other on the bolt shank can be wired to effectively cancel out the effects of fastener bending.

NF-A-1350 FASTENER ELONGATION/EXTENSION

Tightening by fastener elongation is a precise assembly technique which involves tightening to a predetermined value of

tensile strain. Greatest accuracy is achieved when the prestrain value is obtained from load-extension curves of the fastener being used. However, in most instances, calculation of the desired extension is made from Hooke's law. This gives an approximate solution subject to variation due to nonuniform cross sections.

Using this method one must accurately measure the axial elongation of the bolt shank or stud. If both ends of the fastener are accessible, a micrometer can be used to measure this fastener elongation.

Tightening by extension is slow and expensive; consequently, its use is normally confined to special applications, such as the assembly of very large-diameter bolts or studs where torque wrenches or turn-of-the-nut are impractical.

APPENDIX NF-B DESIGN ALLOWABLE STRESSES FOR PLATE-, SHELL-, AND LINEAR-TYPE SUPPORTS

Page 173

[98]

ARTICLE NF-B-1000 INTRODUCTION

[98]

NF-B-1100 OBJECTIVE

The objective of this Appendix is to provide background on the allowable stresses and design stress intensities used for the design of supports given in NF-3000.

[98]

[98]

NF-B-1200 SCOPE

Included in this Appendix is the background on the allowable stresses and design stress intensities, which are a function of material test data, for linear-, plate-, and shell-type supports. Most of the information herein pertains to linear supports while information on allowable stresses and design stress intensities for plate and shell supports is referenced in Appendix III, Article III-2000 (Section III, Division 1, Appendices) for Class 1 of this Section. Guidance is also given for special situations which arise in support design.

[98]

Page 176

[98]

ARTICLE NF-B-2000 LINEAR SUPPORTS - METHOD FOR ESTABLISHING ALLOWABLE STRESSES

Allowable stresses are based on mechanical properties of material, including yield and ultimate strength values, as well as the particular loads applied to the linear member, i.e., tension, bending, compression, shear, or combinations of these loads. The pertinent mechanical properties of materials, the material yield and ultimate strength, allowed for linear supports have been established and these are presented in Section II, Part D of this division. The various stress factors given in NF-3300 for linear elastic analysis are applied in most cases to the yield or ultimate strength values at temperature. Stress multipliers referred to as stress limit factors applicable to the various Service Limits are given in Tables NF-3523(b)-1 and NF-3623(b)-1 for linear supports. In general, these factors maintain elastic response for lower limits, A and B, and they allow higher stress and some possible permanent deformation for higher limits, C and D.

[98]

[98]

NF-B-2100 RESPONSIBILITY FOR ASSIGNING YIELD AND ULTIMATE STRENGTH VALUES

(a) The Boiler and Pressure Vessel Code Committee evaluates the available data and assigns strength values for materials.

(b) Where suitable test data on a specific material are not available, the Committee may base strength values on the available data for similar materials or on an evaluation of known experience with the material.

[98]

[98]

NF-B-2200 TENSION MEMBER ALLOWABLE STRESS

A tension member can fail either by excessive yielding of its gross area or by fracture of the net area at a load smaller than that required to yield the gross area. To prevent failure of a tension member (other than a pin-connected or threaded member), NF-3322.1(a) imposes a factor of safety of 1.67 against yield of the entire member and 2.0 against fracture of its weakest effective net area, which is computed in NF-3322.8 and accounts for shear lag at the connection. For pin-connected and threaded members, the factors of safety are greater.

[98]

[98]

NF-B-2300 BEAM BENDING ALLOWABLE STRESS

Classical beam flexure theory is used to establish bending stresses in linear support members. Allowable bending stresses are established on the basis of this classical theory, utilizing the following assumptions:

(a) stresses are elastic;

(b) deflections are small;

(c) plane sections, normal to the member axis, remain plane after loading.

For a straight member in flexure, the bending stress is tensile on one side of the neutral axis and compressive on the other side. The allowable values given in NF-3322.1(d) consider whether the stress is tensile or compressive, since a compressive stress (limited to two-thirds of the critical buckling value) subjects a beam element to possible buckling. Hence, the formulas for allowable stresses consider lateral-torsional buckling, by accounting for the unsupported length of the compression flange, and they also consider local buckling, by providing maximum values of width-thickness ratios of unstiffened elements of compression flanges.

[98]

Page 177

[98]

NF-B-2400 COMPRESSION MEMBER ALLOWABLE STRESS

Allowable stresses for linear support members which are loaded in axial compression are based on classical theory of centrally loaded columns. While most columns have some applied primary or secondary bending moment, and hence are beam-columns as described in NF-B-2500, a column with a load eccentricity up to $\frac{1}{1000}$ of its length is considered to be centrally loaded.

Compression members have two failure modes: elastic buckling for long members; and inelastic buckling for short and intermediate members. These two modes are reflected in the allowable stress formulas in NF-3322.1(c) which were originally developed for rolled carbon-steel structural shapes. End conditions of the column, i.e., whether it is free, pinned, or fixed, play an important role in the member allowable stress. These end conditions determine the value of K , the effective length factor, which is a parameter used in the allowable stress formulas. The effective length factor, K , is shown for different end conditions in Fig. NF-B-2400-1. The nomograph in Fig. NF-B-2400-2 gives effective length factors for semi-rigid end conditions in

which beams or girders which frame into the ends of columns provide partial moment restraint. The nominal safety factors for Design and Service Level A limits range from 1.67 for short columns, which exhibit post-buckling strength, to 1.92 for long columns, which buckle elastically and often without warning. A further limitation on compression member stress is given by the requirement that these stresses be limited to two-thirds of the member capacity regardless of the service limit.

Flexural support members also developed compressive stresses in flanges. The two failure modes associated with these stresses are: local buckling; and lateral torsional buckling. Local buckling is prevented by limiting the flange width/thickness ratios [NF-3322.2(d)] and lateral-torsional buckling is prevented by the allowable bending stresses [NF-3322.1(d)].

[98]

[98]

NF-B-2500 BEAM-COLUMN ALLOWABLE STRESS

Beam-columns are those linear support members which are subjected to combined flexure and axial compression. The interaction formulas of NF-3322.1(e)(1) account for these combined stresses and the resulting amplification of the bending stress induced by the applied axial load. The primary or secondary bending moment is one of the important parameters which is used in the interaction formulas. When the moment results in secondary stress, the limit of the plastic hinge criterion is increased by fifty percent. However, to ensure conservatism, the stability limits are not increased when the moment is shown to result in secondary stress. Limit analysis design methods in NF-3340 provide similar requirements for linear members loaded in combined axial compression and bending.

[98]

[98]

NF-B-2600 BOLTING ALLOWABLE STRESS

Bolted connections are subjected to tensile and shear loads. Shear connections are designed to be one of the two types:

(a) bearing connections; and

(b) friction connections.

Since bearing connections can be subjected to simultaneous shear and tension, an interaction formula is given in NF-3324.6 to account for the combined stresses in the bolts. Friction connections can also be subjected to simultaneous shear and tension. However, the bolts will not be subjected to shear if the design had provided an adequate clamping force, T_i .

The Code does not require specific values of bolt preload force for either bearing-type or friction-type connections. The design must consider such factors as applied tensile load, susceptibility of the bolt material to stress corrosion cracking (when preload is excessive) and possible opening of joints under high dynamic loads (when preload is not great enough). These factors as well as the applied shear in a friction connection will affect the selection of bolt preload and the method of applying that load, i.e., by torque or tensioner.

FIG. NF-B-2400-1 EFFECTIVE LENGTH FACTOR FOR VARIOUS END CONDITIONS

[98]

FIG. NF-B-2400-1 EFFECTIVE LENGTH FACTOR FOR VARIOUS END CONDITIONS

NOTE:

(1) The subscripts *A* and *B* refer to the joints at the two ends of the column section being considered.

G is defined as

$$G = \frac{\sum \frac{I_c}{L_c}}{\sum \frac{I_q}{L_q}}$$

in which Σ indicates a summation of all members rigidly connected to that joint and lying in the plane in which buckling of the column is being considered. I_c is the moment of inertia, and L_c the unsupported length of a column section, and I_q is the moment of inertia and L_q the unsupported length of a girder or other restraining member. I_c and I_q are taken about axes perpendicular to the plane of buckling being considered.

For column ends supported by but not rigidly connected to a footing or foundation, *G* is theoretically infinity, but, unless actually designed as a true friction free pin, may be taken as "10" for practical designs. If the column end is rigidly attached to a properly designed footing, *G* may be taken as 1.0. Smaller values may be used if justified by analysis.

FIG. NF-B-2400-2 ALIGNMENT CHART FOR EFFECTIVE LENGTH OF COLUMNS IN CONTINUOUS FRAMES

[98]

FIG. NF-B-2400-2 ALIGNMENT CHART FOR EFFECTIVE LENGTH OF COLUMNS IN CONTINUOUS FRAMES

[98]

ARTICLE NF-B-3000 PLATE AND SHELL SUPPORTS - ALLOWABLE STRESSES

Allowable stresses for Class 1, 2, and 3 plate and shell type supports are established in accordance with NF-3220, NF-3250, and NF-3260, respectively. For Class 1 construction allowable stresses are a function of the material design stress intensity (S_m) and for Class 2 and 3 construction the allowable stresses are a function of the material allowable (S). The procedure for establishing design stress intensities (S_m) and allowable stress (S) are given in Appendix III, Article III-2000 (Section III, Division 1, Appendices). Stress multipliers, i.e., stress limit factors which are applicable to various levels of service limits are given in Tables NF-3522(b)-1, NF-3552(b)-1, and NF-3652(b)-1. In general, these factors maintain elastic response for lower limits, A and B, and they allow higher stresses and some possible permanent deformation for higher limits, C and D.

[98]

Page 181

[98]

ARTICLE NF-B-4000 MATERIALS WITH LOW RATIOS OF TENSILE TO YIELD STRENGTH

Allowable stresses for linear support members were originally developed for materials which exhibit a considerable amount of strain hardening. The ratio of tensile to yield strength for these materials (S_u/S_y) is as high as 1.61 for SABE. However, materials with much lower values of S_u/S_y ratio are now included in the Code and these are covered by the NF design rules and allowable stresses in NF-3000. The lower bound of S_u/S_y is 1.07. For certain allowable stresses the factor of safety against failure is lower for materials with low S_u/S_y ratios than it is for high strain hardening materials. The allowable tensile stress (see NF-B-2200) takes into account materials with low strain hardening by imposing a nominal factor of safety of 2.0 on tensile strength on effective net area. Table NF-B-4000 shows that minimum factor of safety is 1.34 for a material with the lower bound S_u/S_y ratio of 1.07. The minimum factor of safety for a high strain hardening material is about 1.43.

Designers should use caution when materials with low S_u/S_y ratios are utilized in support design. The material ductility and other material qualities, including S_u/S_y ratios, should be considered so that the minimum factors of safety will not be less than those shown in Table NF-B-4000.

[98]

Page 182

TABLE NF-B-4000
FACTORS OF SAFETY FOR A MATERIAL WITH A LOW
VALUE OF S_u/S_y RATIO

Service Level	Tension	Bending	Compression
A	2.00	1.78	1.67
B	1.50	1.34	1.50
C	1.43	1.43	1.50
D	1.43	1.43	1.50

GENERAL NOTES:

- (a) The ratio of tensile to yield strength (S_u/S_y) is 1.07 for the factors of safety shown. This is a lower bound for linear support materials allowed by the Code.
- (b) Materials with higher S_u/S_y ratios will have higher factors of safety.

[98]

TABLE NF-B-4000 FACTORS OF SAFETY FOR A MATERIAL WITH A LOW VALUE OF S_u/S_y RATIO

[98]

ARTICLE NF-B-5000 SPECIAL CONSIDERATION

[98]

NF-B-5100 COPPER-BASED ALLOYS

Copper-based alloys are not intended for use as main structural members. However, the Code does provide for their use in the load patch of a support. Use of copper-based alloys is restricted by NF-2122(b) to bearing-type applications. This restriction was incorporated because experience with these materials as main members in supports is lacking and behavior of elements fabricated of these materials has not been confirmed with test data.

[98]

[98]

NF-B-5200 STAINLESS STEEL

Allowable stresses for stainless steel are based on the same consideration given to other Code materials. These are discussed

in NF-B-1000 and NF-B-2000. However, stainless steel in compression requires special consideration because the compression stress-strain curve is nonlinear rather than bilinear as it is for carbon steels. For linear support members this difference in stress-strain relationships results in overestimating the column capacity of members fabricated from austenitic stainless steel.

To account for the different characteristics with austenitic stainless steel exhibits when it is subjected to compressive stress, NF-3322.1 provides special rules for stainless steel columns. These alternate rules provide a minimum factor-of-safety of 2.15 for Design and Level A Service Limits. The allowable compressive stress is a bilinear function of slenderness ratio, Kl/r , rather than a parabolic function which is used for other materials.

[98]

[98]

NF-B-5300 NONDUCTILE BEHAVIOR AND STRESS CORROSION CRACKING

High strength materials are susceptible to brittleness and stress corrosion cracking. Conditions which exacerbate these problems include:

- (a) installation in a corrosive environment such as damp air;
- (b) long-term high stress including bolt preload and dead bolts;
- (c) residual stress caused by fabrication;
- (d) certain material manufacturing processes which enhance hardness.

The design specification can reduce the susceptibility of the support material to brittle fracture by requiring impact testing per NF-2300. Also, designers should exercise caution when using high strength materials when supports are subjected to impact loads.

IMPORTANT INFORMATION ON THE 1998 BOILER AND PRESSURE VESSEL CODE ADDENDA DISTRIBUTION SCHEDULE

There is a change in the way the Addenda to the 1998 Edition of the ASME Boiler and Pressure Vessel Code are distributed. The 1998 Edition, published July 1, 1998, incorporates the 1998 Addenda revisions, additions, or deletions. There will be no separate 1998 Addenda issued in a replacement page format. Two additional Addenda to the 1998 Edition, in the form of replacement pages, will be issued on July 1, 1999 and July 1, 2000.

The Summary of Changes published with the 1998 Edition lists and describes the revisions that are part of the 1998 Addenda. These changes are identified with a margin note, **98**, denoting the affected area.

The Addenda for 1999 and 2000 will also have a Summary of Changes and identifiers printed on the replacement pages. The revisions, additions, or deletions will be incorporated directly into the affected pages. It is advisable to retain the title sheets and all replaced pages for reference.

The effective dates for Code Editions and Addenda are described in the Foreword.

Date of Issue - July 1, 1998

(Includes all Addenda dated December 1997 and earlier)

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

The footnotes in this document are part of this American National Standard.

Division 2 - Alternative Rules

Division 3 - Alternative Rules for Construction of High Pressure Vessels

IX Welding and Brazing Qualifications

X Fiber-Reinforced Plastic Pressure Vessels

XI Rules for Inservice Inspection of Nuclear Power Plant Components

ADDENDA

Colored-sheet Addenda, which include additions and revisions to individual Sections of the Code, are published annually and will be sent automatically to purchasers of the applicable Sections up to the publication of the 2001 Code. The 1998 Code is available only in the loose-leaf format; accordingly, the Addenda will be issued in the loose-leaf, replacement-page format.

INTERPRETATIONS

ASME issues written replies to inquiries concerning interpretation of technical aspects of the Code. The Interpretations for each individual Section will be published separately and will be included as part of the update service to that Section. They will be issued semiannually (July and December) up to the publication of the 2001 Code. Interpretations of Section III, Divisions 1 and 2, will be included with the update service to Subsection NCA.

CODE CASES

The Boiler and Pressure Vessel Committee meets regularly to consider proposed additions and revisions to the Code and to formulate Cases to clarify the intent of existing requirements or provide, when the need is urgent, rules for materials or constructions not covered by existing Code rules. Those Cases which have been adopted will appear in the appropriate 1998

FOREWORD

The American Society of Mechanical Engineers set up a committee in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. This committee is now called the Boiler and Pressure Vessel Committee.

The Committee's function is to establish rules of safety governing the design, fabrication, and inspection during construction of boilers and pressure vessels, and to interpret these rules when questions arise regarding their intent. In formulating the rules, the Committee considers the needs of users, manufacturers, and inspectors of pressure vessels. The objective of the rules is to afford reasonably certain protection of life and property and to provide a margin for deterioration in service so as to give a reasonably long, safe period of usefulness. Advancements in design and material and the evidence of experience have been recognized.

This Code contains mandatory requirements, specific prohibitions, and nonmandatory guidance for construction,¹ and inservice inspection and testing activities. The Code does not address all aspects of these activities and those aspects which are not specifically addressed should not be considered prohibited. The Code is not a handbook and cannot replace education, experience, and the use of engineering judgment. The phrase *engineering judgment* refers to technical judgments made by knowledgeable engineers experienced in the application of the Code. Engineering judgments must be consistent with Code philosophy and such judgments must never be used to overrule mandatory requirements or specific prohibitions of the Code.

¹ Construction, as used in this Foreword, is an all-inclusive term comprising materials, design, fabrication, examination, inspection, testing, certification, and pressure relief.

The Committee recognizes that tools and techniques used for design and analysis change as technology progresses and expects engineers to use good judgment in the application of these tools. The designer is responsible for complying with Code rules and demonstrating compliance with Code equations when such equations are mandatory. The Code neither requires nor prohibits the use of computers for the design or analysis of components constructed to the requirements of the Code. However, designers and engineers using computer programs for design or analysis are cautioned that they are responsible for all technical assumptions inherent in the programs they use and they are responsible for the application of these programs to their design.

The Code does not fully address tolerances. When dimensions, sizes, or other parameters are not specified with tolerances, the values of these parameters are considered nominal and allowable tolerances or local variances may be considered acceptable when based on engineering judgment and standard practice as determined by the engineer.

The Boiler and Pressure Vessel Committee deals with the care and inspection of boilers and pressure vessels in service only to the extent of providing suggested rules of good practice as an aid to owners and their inspectors.

The rules established by the Committee are not to be interpreted as approving, recommending, or endorsing any proprietary or specific design or as limiting in any way the manufacturer's freedom to choose any method of design or any form of construction that conforms to the Code rules.

The Boiler and Pressure Vessel Committee meets regularly to consider revisions of the rules, new rules as dictated by technological development, Code Cases, and requests for interpretations. Only the Boiler and Pressure Vessel Committee has the authority to provide official interpretations of this Code. Requests for revisions, new rules, Code Cases, or interpretations shall be addressed to the Secretary in writing and shall give full particulars in order to receive consideration and action (see Mandatory Appendix covering preparation of technical inquiries). Proposed revisions to the Code resulting from inquiries will be presented to the Main Committee for appropriate action. The action of the Main Committee becomes effective only after confirmation by letter ballot of the Committee and approval by ASME.

Proposed revisions to the Code approved by the Committee are submitted to the American National Standards Institute and published in *Mechanical Engineering*

to invite comments from all interested persons. After the allotted time for public review and final approval by ASME,

to invite comments from all interested persons. After the allotted time for public review and final approval by ASME, revisions are published annually in Addenda to the Code.

Code Cases may be used in the construction of components to be stamped with the ASME Code symbol beginning with the date of their approval by ASME.

Code Editions may be used on or after the date of issue shown in the Edition. After Code revisions are approved by ASME, they may be used beginning with the date of issue shown on the Addenda. Revisions to material specifications are originated by the American Society for Testing and Materials (ASTM) and other recognized national or international organizations, and are usually adopted by ASME. However, those revisions may or may not have any effect on the suitability of material, produced to earlier editions of specifications, for use in ASME construction. ASME material specifications approved for use in each construction Code are listed in the Appendices of Section II, Parts A and B. These Appendices list, for each specification, the latest edition adopted by ASME, and earlier and later editions considered by ASME to be identical for ASME construction.

Owners of nuclear power plants are cautioned that Code Editions, Addenda, and Cases to be used in construction shall be acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

Each state and municipality in the United States and each province in Canada that adopts or accepts one or more Sections of the Boiler and Pressure Vessel Code is invited to appoint a representative to act on the Conference Committee to the Boiler and Pressure Vessel Committee. Since the members of the Conference Committee are in active contact with the administration and enforcement of the rules, the requirements for inspection in this Code correspond with those in effect in their respective jurisdictions. The required qualifications for an Authorized Inspector under these rules may be obtained from the administrative authority of any state, municipality, or province which has adopted these rules.

The Boiler and Pressure Vessel Committee in the formulation of its rules and in the establishment of maximum design and operating pressures considers materials, construction, method of fabrication, inspection, and safety devices. Permission may be granted to regulatory bodies and organizations publishing safety standards to use a complete Section of the Code by reference. If usage of a Section, such as Section IX, involves exceptions, omissions, or changes in provisions, the intent of the Code might not be attained.

Where a state or other regulatory body, in the printing of any Section of the Boiler and Pressure Vessel Code, makes additions or omissions, it is recommended that such changes be clearly indicated.

The National Board of Boiler and Pressure Vessel Inspectors is composed of chief inspectors of states and municipalities in the United States and of provinces in Canada that have adopted the Boiler and Pressure Vessel Code. This Board, since its organization in 1919, has functioned to uniformly administer and enforce the rules of the Boiler and Pressure Vessel Code. The cooperation of that organization with the Boiler and Pressure Vessel Committee has been extremely helpful.

The Code Committee does not rule on whether a component shall or shall not be constructed to the provisions of the Code. The Scope of each Section has been established to identify the components and parameters considered by the Committee in formulating the Code rules. Laws or regulations issued by municipality, state, provincial, federal, or other enforcement or regulatory bodies having jurisdiction at the location of an installation establish the mandatory applicability of the Code rules, in whole or in part, within their jurisdiction. Those laws or regulations may require the use of this Code for vessels or components not considered to be within its Scope or may establish additions or deletions in that Scope. Accordingly, inquiries regarding such laws or regulations are to be directed to the issuing enforcement or regulatory body.

Questions or issues regarding compliance of a specific component with the Code rules are to be directed to the ASME Certificate Holder (Manufacturer). Inquiries concerning the interpretation of the Code are to be directed to the ASME Boiler and Pressure Vessel Committee. ASME is to be notified should questions arise concerning improper use of an ASME Code symbol.

The specifications for materials given in Section II are identical with or similar to those of specifications published by ASTM, AWS, and other recognized national or international organizations. When reference is made in an ASME material specification to a non-ASME specification for which a companion ASME specification exists, the reference shall be interpreted as applying to the ASME material specification. Not all materials included in the material specifications in Section II have been adopted for use in this Section. Usage is limited to those materials and grades listed in at least one of the tables of Section II, Part D, Subpart 1, identified as applicable to this Section. All materials allowed by this Section and used for construction within the scope of these rules shall be furnished in accordance with material specifications

contained in Section II or referenced in Appendices A of Section II, Parts A and B except where otherwise provided in Code Cases or in this Section of the Code. Materials covered by these specifications are acceptable for use in items covered by the Code Sections only to the degree indicated in the applicable Section. Materials for Code use should preferably be ordered, produced, and documented on this basis. Material produced to an acceptable specification with requirements different from the requirements of the corresponding specification listed in Appendix A of Part A or Part B may also be used in accordance with the above, provided the material manufacturer or vessel manufacturer certifies with evidence acceptable to the Authorized Inspector that the corresponding ASME specification requirements of specifications listed in Appendix A of Part A or Part B have been met. Material produced to an acceptable material specification is not limited as to country of origin.

When required by context in this Section, the singular shall be interpreted as the plural, and vice-versa; and the feminine, masculine, or neuter gender shall be treated as such other gender as appropriate.

Publication of the SI (Metric) Edition of the ASME Boiler and Pressure Vessel Code was discontinued with the 1986 Edition. Effective October 1, 1986, the SI Edition was withdrawn as an ASME Boiler and Pressure Vessel Code document.

STATEMENT OF POLICY ON THE USE OF CODE SYMBOLS AND CODE AUTHORIZATION IN ADVERTISING

ASME has established procedures to authorize qualified organizations to perform various activities in accordance with the requirements of the ASME Boiler and Pressure Vessel Code. It is the aim of the Society to provide recognition of organizations so authorized. An organization holding authorization to perform various activities in accordance with the requirements of the Code may state this capability in its advertising literature.

Organizations that are authorized to use Code Symbols for marking items or constructions which have been constructed and inspected in compliance with the ASME Boiler and Pressure Vessel Code are issued Certificates of Authorization. It is the aim of the Society to maintain the standing of the Code Symbols for the benefit of the users, the enforcement jurisdictions, and the holders of the symbols who comply with all requirements.

Based on these objectives, the following policy has been established on the usage in advertising of facsimiles of the symbols, Certificates of Authorization, and reference to Code construction. The American Society of mechanical Engineers does not "approve," "certify," "rate," or "endorse" any item, construction, or activity and there shall be no statements or implications which might so indicate. An organization holding a Code Symbol and/or a Certificate of Authorization may state in advertising literature that items, constructions, or activities "are built (produced or performed) or activities conducted in accordance with the requirements of the ASME Boiler and Pressure Vessel Code," or "meet the requirements of the ASME Boiler and Pressure Vessel Code."

The ASME Symbol shall be used only for stamping and nameplates as specifically provided in the Code. However, facsimiles may be used for the purpose of fostering the use of such construction. Such usage may be by an association or a society, or by a holder of a Code Symbol who may also use the facsimile in advertising to show that clearly specified items will carry the symbol. General usage is permitted only when all of a manufacturer's items are constructed under the rules.

The ASME logo, which is the cloverleaf with the letters ASME within, shall not be used by any organization other than ASME.

STATEMENT OF POLICY ON THE USE OF ASME MARKING TO IDENTIFY MANUFACTURED ITEMS

The ASME boiler and Pressure Vessel Code provides rules for the construction of boilers, pressure vessels, and nuclear components. This includes requirements for materials, design, fabrication, examination, inspection, and stamping. Items constructed in accordance with all of the applicable rules of the Code are identified with the official Code Symbol Stamp described in the governing Section of the Code.

Markings such as "ASME," "ASME Standard," or any other marking including "ASME" or the various Code Symbols shall not be used on any item which is not constructed in accordance with all of the applicable requirements of the Code.

Items shall not be described on ASME Data Report Forms nor on similar forms referring to ASME which tend to imply that all Code requirements have been met when, in fact, they have not been. Data Report Forms covering items not fully complying with ASME requirements should not refer to ASME or they should clearly identify all exceptions to the ASME requirements.

ORGANIZATION OF SECTION III

1. GENERAL

Section III consists of Division 1, Division 2, and Division 3. These Divisions are broken down into Subsections and are designated by capital letters preceded by the letter "N" for Division 1, by the letter "C" for Division 2, and by the letter "W" for Division 3. The following eleven books make up the three Divisions.

Subsection NCA - General Requirements for Division 1 and Division 2

Division 1

Subsection NB - Class 1 Components

Subsection NC - Class 2 Components

Subsection ND - Class 3 Components

Subsection NE - Class MC Components

Subsection NF - Supports

Subsection NG - Core Support Structures

Subsection NH - Class 1 Components in Elevated Temperature Service

Appendices

Division 2 - Code for Concrete Reactor Vessels and Containments

Division 3 - Containment Systems and Transport Packagings for Spent Nuclear Fuel and High Level Radioactive Waste

The Division 2 book includes Subsection CC - Concrete Containments and Division 2 Appendices.

The Division 3 book includes Subsections WA and WB for General Requirements and Class TP (Type B) Containment, respectively.

2. SUBSECTIONS

Subsections are divided into Articles, Subarticles, paragraphs, and, where necessary, subparagraphs and subsubparagraphs.

3. ARTICLES

Articles are designated by the applicable letters indicated above for the Subsections followed by Arabic numbers, such as NB-1000. Where possible, Articles dealing with the same topics are given the same number in each Subsection in accordance with the following general scheme:

Article Number	Title
1000	Introduction or Scope
2000	Material
3000	Design
4000	Fabrication and Installation
5000	Examination
6000	Testing
7000	Overpressure Protection
8000	Nameplates, Stamping, and Reports

The numbering of Articles and the material contained in the Articles may not, however, be consecutive. Due to the fact that the complete outline may cover phases not applicable to a particular Subsection or Article, the rules have been prepared with some gaps in the numbering.

4. SUBARTICLES

Subarticles are numbered in units of 100, such as NB-1100.

5. SUBSUBARTICLES

Subsubarticles are numbered in units of 10, such as NB-2130, and generally have no text. When a number such as NB-1110 is followed by text, it is considered a paragraph.

6. PARAGRAPHS

Paragraphs are numbered in units of 1, such as NB-2121.

7. SUBPARAGRAPHS

Subparagraphs, when they are *major* subdivisions of a paragraph, are designated by adding a decimal followed by one or more digits to the paragraph number, such as NB-1132.1. When they are *minor* subdivisions of a paragraph, subparagraphs may be designated by lowercase letters in parentheses, such as NB-2121(a).

8. SUBSUBPARAGRAPHS

Subsubparagraphs are designated by adding lowercase letters in parentheses to the *major* subparagraph numbers, such as NB-1132.1(a). When further subdivisions of *minor* subparagraphs are necessary, subsubparagraphs are designated by adding Arabic numerals in parentheses to the subparagraph designation, such as NB-2121(a)(1).

Page xxiv

9. REFERENCES

References used within Section III generally fall into one of the following four categories.

A. References to Other Portions of Section III

When a reference is made to another Article, Subarticle, or paragraph, all numbers subsidiary to that reference shall be included. For example, reference to NB-3000 includes all material in Article NB-3000; reference to NB-3200 includes all material in Subarticle NB-3200; reference to NB-3230 includes all paragraphs NB-3231 through NB-3236.

B. References to Other Sections

Other Sections referred to in Section III are:

Section II, Materials. When a requirement for a material, or for the examination or testing of a material, is to be in accordance with a specification such as SA-105, SA-370, or SB-160, the reference is to material specifications in Section II. These references begin with the letter "S."

Section V, Nondestructive Examination. Section V references begin with the letter "T" and relate to the nondestructive examination of material or welds.

Section IX, Welding and Brazing Qualifications. Section IX references begin with the letter "Q" and relate to welding and brazing requirements.

Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components. When a reference is made to inservice inspection, the rules of Section XI shall apply.

C. Reference to Specifications and Standards Other Than Published in Code Sections

(1) Specifications for examination methods and acceptance standards to be used in connection with them are published by the American Society for Testing and Materials. At the time of publication of Section III, some such specifications were not included in Section II of this Code. A reference to ASTM E 71-64 refers to the specification so designated by and published by ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

2 The American National Standards Institute (ANSI) was formerly known as the American Standards Association. Standards approved by the Association were designated by the prefix "ASA" followed by the number of the standard and the year of publication. More recently, the American National Standards Institute was known as the United States of America Standards Institute. Standards were designated by the prefix "USAS" followed by the number of the standard and the year of publication. While the letters of the prefix have changed with the name of the organization, the numbers of the standards have remained unchanged.

(2) Dimensional standards covering products such as valves, flanges, and fittings are sponsored and published by the American Society of Mechanical Engineers and approved by the American National Standards Institute.² When a product is to conform to such a standard, for example ANSI B16.5, the standard is approved by the American National Standards Institute. The applicable year of issue is that suffixed to its numerical designation in Table NB-3132-1, for example ANSI B16.5-1977. Standards published by the American Society of Mechanical Engineers are available from ASME, 22 Law Drive, Box 2300, Fairfield, NJ 07007-2300.

(3) Dimensional and other types of standards covering products such as valves, flanges, and fittings are also published by the Manufacturers Standardization Society of the Valve and Fittings Industry and are known as Standard Practices. When a product is required by these rules to conform to a Standard Practice, for example MSS SP-6, the Standard Practice referred to is published by the Manufacturers Standardization Society of the Valve and Fittings Industry, 127 Park Street, N.E., Vienna, VA 22180. The applicable year of issue of such a Standard Practice is that suffixed to its numerical designation in Table NB-3132-1, for example MSS SP-6-1963.

(4) Specifications for welding and brazing materials are published by the American Welding Society, 550 N.W. LeJeune Road, Miami, FL 33135. Specifications of this type are incorporated in Section II and are identified by the AWS designation with the prefix "SF," for example SFA-5.1.

(5) Standards applicable to the design and construction of tanks and flanges are published by the American Petroleum Institute and have designations such as API-620 and API-2000. When documents so designated are referred to in Section III, they are standards published by the American Petroleum Institute.

D. References to Appendices

Two types of Appendices are used in Section III and are designated Mandatory and Nonmandatory.

(1) Mandatory Appendices contain requirements which must be followed in construction; such references are designated by a Roman numeral followed by Arabic numerals. References to II-1100 or XI-3212, for example, relate to the Mandatory Appendices.

(2) Nonmandatory Appendices provide information or guidance for the use of Section III; such references are designated by a capital letter followed by Arabic numerals. A reference to D-1100, for example, relates to a Nonmandatory Appendix.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NG-1000

ARTICLE NG-1000 INTRODUCTION

Page 1

NG-1100 SCOPE

NG-1110 ASPECTS OF CONSTRUCTION COVERED BY THESE RULES

Subsection NG establishes rules for materials, design, fabrication, examination, and preparation of reports required in the manufacture and installation of core support structures.¹²

NG-1120 DEFINITION OF STRUCTURES AND APPLICATION OF THESE RULES TO THEM

NG-1121 Core Support Structures

Core support structures shall be constructed to the rules of this Subsection. Core support structures are those structures or parts of structures which are designed to provide direct support or restraint of the core (fuel and blanket assemblies) within the reactor pressure vessel. Structures which support or restrain the core only after the postulated failure of core support

structures are considered to be internal structures (NG-1122).

1 (a) The rules of Subsection NG are not directed to sealing against coolant leakage. Further, gross hydrostatic loading may not be typical of the loads experienced by core support structures. Thus, hydrostatic testing of the structures is not required.

(b) The most severe loads on which design must be predicated usually result from abnormal, rather than normal, load conditions. Core support structures need not remain leak tight to perform their function. However, if leak tightness is required for a structure, the rules for pressure boundary construction may be appropriate.

2 In Subsection NG it is recognized that the design functions are frequently handled separately from the fabrication functions of the Certificate Holder manufacturing core supports. The separation of these functions is necessary because the design of core support structures cannot be performed completely independent of the nuclear or hydraulic design of the coolant system. Furthermore, portions of a set of structures may be fabricated by a specialist and assembled at the site without any one fabricator having a controlling position for fabrication of the complete structure. Therefore, provisions are made herein for separate organizations to perform the design and fabricating functions of the Certificate Holder. This Section (NCA-3510), however, requires that one organization have overall responsibility for compliance with the requirements of this Subsection NG. The use of the term Certificate Holder therefore must be understood to mean the design or fabricating organization assuming the overall responsibility for compliance with this Section. The term Certificate Holder, as used in this Subsection, applies to the Certificate Holder manufacturing core supports who shall be responsible for certifying that all core support structures and internal structures, as defined in NG-1120, comply with the requirements of this Subsection.

3 Note that some fuel and blanket positions in the core matrix may be filled with structures related to reflector or shielding functions. These structures also fall into the fuel and blanket category described above.

NG-1122 Internal Structures

(a) Internal structures are *all* structures within the reactor pressure vessel other than core support structures, fuel³ and blanket assemblies, control assemblies, and instrumentation.

(b) The rules of this Subsection apply to internal structures as defined in (a) above, only when so stipulated by the Certificate Holder manufacturing core supports, hereafter referred to in this Subsection as Certificate Holder.

(c) The Certificate Holder shall certify² that the construction of all internal structures is such as not to affect adversely the integrity of the core support structure.

NG-1123 Temporary Attachments

A temporary attachment is an element in contact with or connected to the core support structure which is removed prior to operation. Temporary attachments include items such as alignment lug tie straps and braces.

Page 4

NG-1130 BOUNDARIES OF JURISDICTION APPLICABLE TO THIS SUBSECTION

NG-1131 Boundary Between Core Support Structure and Reactor Pressure Vessel

The jurisdictional boundary between a core support structure and the reactor pressure vessel shall be the surface of the core support structure. The first connecting weld of a core support structure to the reactor pressure vessel shall be considered part of the reactor pressure vessel unless the weld is more than $2t$ from the pressure retaining portion of the reactor pressure vessel, where t is the nominal thickness of the pressure retaining material. Beyond the first connecting weld to the reactor pressure vessel, or beyond $2t$ from the pressure retaining portion of the reactor pressure vessel, the first weld shall be considered part of the core support structure, unless otherwise specified in the Design Specification. Mechanical fasteners used to connect a core support structure to the reactor pressure vessel shall meet the requirements of this Subsection. Figure NG-1131-1 is provided as an aid in defining the boundary and construction requirements of this Subsection.

NG-1132 Boundary Between Core Support Structure and Internal Structure

(a) Internal structures may bear on or may be welded, cast, or fastened to core support structures.

(b) The jurisdictional boundary between a core support structure and an internal structure is the surface of the core support structure. The means by which the internal structure is connected to the core support structure shall fall within the jurisdiction of this Subsection.

NG-1133 Boundary Between Core Support Structure and Temporary Attachment

The jurisdictional boundary between a core support structure and a temporary attachment shall be the surface of the core support structure.

GENERAL NOTE:

These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

NOTE:

- (1) If the attachment is an internal structure [NG-1122], material, design, and connections, as appropriate, are outside Code jurisdiction except when the Certificate Holder stipulates they shall conform to Subsection NG.

FIG. NG-1131-1 JURISDICTIONAL BOUNDARY BETWEEN CORE SUPPORT STRUCTURE AND REACTOR PRESSURE VESSEL

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NG-2000

ARTICLE NG-2000 MATERIAL

Page 7

NG-2100 GENERAL REQUIREMENTS FOR MATERIAL

[98]

NG-2110 SCOPE OF PRINCIPAL TERMS EMPLOYED

(a) The term *material* as used in this Subsection is defined in NCA-1220. The term *Material Organization* is defined in NCA-9000.

(b) The requirements of this Article make reference to the term *thickness*. For the purpose intended, the following definitions of nominal thickness apply:

(1) *plate* - the thickness is the dimension of the short transverse direction

(2) *forgings* - the thickness is the dimension defined as follows:

(a) *hollow forgings* - the nominal thickness is measured between the inside and outside surfaces (radial thickness)

(b) *disk forgings* (axial length less than the outside diameter) - the nominal thickness is the axial length

(c) *flat ring forgings* (axial length less than the radial thickness) - for axial length ≤ 2 in. (51 mm), the axial length is the nominal thickness; for axial length > 2 in. (51 mm), the radial thickness is the nominal thickness

(d) *rectangular solid forgings* - the least rectangular dimension is the nominal thickness

(3) *castings* - thickness, t , is defined as the largest nominal thickness of the load carrying portion of the casting.

[98]

NG-2120 MATERIAL FOR CORE SUPPORT STRUCTURES

NG-2121 Permitted Material Specifications

(a) Core support structural material, and material welded thereto, and threaded structural fasteners, with the exception of welding material (NG-2430), hard surfacing material (Section IX, QW-251.4), cladding which is 10% or less of the thickness of the base material (NG-3122), or the material excluded by NG-4231.2, shall conform to the requirements of the specifications for material given in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1 and to all of the special requirements of this Article which apply to the product form in which the material is used.

(b) The requirements of this Article apply to the internal structures (NG-1122) only as specifically stipulated by the Certificate Holder; however, the Certificate Holder shall certify that the material used for the internal structures shall not adversely affect the integrity of the core support structure.

(c) Welding material used in manufacture of items shall comply with an SFA Specification in Section II, Part C, except as otherwise permitted in Section IX, and shall also comply with the applicable requirements of this Article. The requirements of this Article do not apply to materials used as backing rings or backing strips in welded joints.

NG-2122 Special Requirements Conflicting With Permitted Material Specifications

Special requirements stipulated in this Article shall apply in lieu of the requirements of the material specification wherever the special requirements conflict with the material specification requirements (NCA-3856). Where the special requirements include an examination, test, or treatment which is also required by the material specification, the examination, test, or treatment need be performed only once. Required nondestructive examinations shall be performed as specified for each product form in NG-2500. Any examination, repair, test, or treatment required by the material specification or this Article may be performed by the Material Organization or the Certificate Holder as provided in NG-4121.1. Any hydrostatic or pneumatic pressure test required by a material specification need not be performed provided the material is not used in a pressure retaining function.

NG-2124 Size Ranges

Material outside the limits of size or thickness given in any specification in Section II may be used if the material is in compliance with the other requirements of the specification and no size limitation is given in the rules for construction. In those specifications in which chemical composition, mechanical properties, or both are indicated to vary with size or thickness, any material outside the specification range shall be required to conform to the composition and mechanical properties shown for the nearest specified range (NCA-3856).

NG-2130 CERTIFICATION OF MATERIAL

All material used in the construction or installation of core support structures shall be certified as required in NCA-3862 and NCA-3861. Certified Material Test Reports are required for core support material except as provided by NCA-3862. A Certificate of Compliance may be provided in lieu of Certified Material Test Reports for all other material. Copies of all Certified Material Test Reports and Certificates of Compliance applicable to material used in a core support structure shall be furnished with the material.

NG-2140 WELDING MATERIAL

For the requirements governing the material to be used for welding, see NG-2400.

NG-2150 MATERIAL IDENTIFICATION

The identification of material for core support structures shall meet the requirements of NCA-3856. Material for small items shall be controlled during manufacture of the core support structures so that they are identifiable as acceptable material at all times. Welding material shall be controlled during the repair of material and the manufacture and installation of core support structures so that they are identifiable as acceptable material until the material is actually consumed in the process (NG-4122).

NG-2160 DETERIORATION OF MATERIAL IN SERVICE

Consideration of deterioration of material caused by service is generally outside the scope of this Subsection. It is the responsibility of the Owner to select material suitable for the conditions stated in the Design Specifications (NCA-3250), with specific attention being given to the effects of service conditions upon the properties of the material.

NG-2170 HEAT TREATMENT TO ENHANCE IMPACT PROPERTIES

Carbon steels, low alloy steels, and high alloy chromium (Series 4XX) steels may be heat treated by quenching and tempering to enhance their impact properties. Postweld heat treatment of the component at a temperature of not less than 1100°F may be considered to be the tempering phase of the heat treatment.

NG-2180 PROCEDURES FOR HEAT TREATMENT OF MATERIAL

When heat treating temperature or time is required by the material specification and the rules of this Subsection, the heat treating shall be performed in temperature-surveyed and -calibrated furnaces or the heat treating shall be controlled by measurement of material temperature by thermocouples in contact with the material or attached to blocks in contact with the material or by calibrated pyrometric instruments. Heat treating shall be performed under furnace loading conditions such

that the heat treatment is in accordance with the material specification and the rules of this Subsection.

NG-2190 TEMPORARY ATTACHMENT MATERIAL

Material used for temporary attachments need not comply with NG-2000 and may be welded to the core support structure provided the requirements of NG-4430 are met.

Page 13

NG-2200 MATERIAL TEST COUPONS AND SPECIMENS FOR FERRITIC STEEL MATERIAL

NG-2210 HEAT TREATMENT REQUIREMENTS

NG-2211 Test Coupon Heat Treatment for Ferritic Material¹

Where ferritic steel material is subjected to heat treatment during construction, the material used for the tensile and impact test specimens shall be heat treated in the same manner as the core support structures, except that test coupons and specimens for P-No. 1 material with a nominal thickness of 2 in. or less are not required to be so heat treated. The Certificate Holder shall provide the Material Organization with the temperature and heating and cooling rate to be used. In the case of postweld heat treatment, the total time at temperature or temperatures for the test material shall be at least 80% of the total time at temperature or temperatures during actual postweld heat treatment of the material and the total time at temperature or temperatures for the test material, coupon, or specimen may be performed in a single cycle.

NG-2212 Test Coupon Heat Treatment for Quenched and Tempered Material

NG-2212.1 Cooling Rates.

Where ferritic steel material is subjected to quenching from the austenitizing temperature, the test coupons representing those materials shall be cooled at a rate similar to and no faster than the main body of the material except in the case of certain forgings and castings (NG-2223.3 and NG-2226.4). This rule shall apply for coupons taken directly from the material as well as for separate test coupons representing the material, and one of the general procedures described in NG-2212.2 or one of the specific procedures described in NG-2220 shall be used for each product form.

1 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specifications. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

2 Annex A1 of SA-654 may be used to satisfy the requirements of NG-2212.2(a) and (b) for forgings.

NG-2212.2 General Procedures.²

One of the general procedures stipulated in (a), (b), and (c) below may be applied to quenched and tempered material or test coupons representing the material, provided the specimens are taken relative to the surface of the product in accordance with NG-2220. Further specific details of the methods to be used shall be the obligation of the Material Organization and the Certificate Holder.

(a) Any procedure may be used which can be demonstrated to produce a cooling rate in the test material that matches the cooling rate of the main body of the product at the region midway between midthickness and the surface ($1/4t$) and no nearer any heat treated edge than a distance equal to the nominal thickness t being quenched within 25°F and 20 sec at all temperatures after cooling begins from the austenitizing temperature.

(b) If cooling rate data for the material and cooling rate control devices for the test specimens are available, the test specimens may be heat treated in the device to represent the material provided that the provisions of (a) above are met.

(c) When any of the specific procedures described in NG-2220 are used, faster cooling rates at the edges may be compensated for by:

(1) taking the test specimens at least t from a quenched edge where t equals the material thickness;

(2) attaching a steel pad at least t wide by a partial penetration weld (which completely seals the buffered surface) to the edge where specimens are to be removed;

(3) using thermal barriers or insulation at the edge where specimens are to be removed.

It shall be demonstrated (and this information shall be included in the Certified Material Test Report) that the cooling rates are equivalent to (a) or (b) above.

NG-2220 PROCEDURE FOR OBTAINING TEST COUPONS AND SPECIMENS FOR QUENCHED AND TEMPERED MATERIAL

NG-2221 General Requirements

The procedure for obtaining test coupons and specimens for quenched and tempered material is related to the product form. Coupon and specimen location and the number of tension test specimens shall be in accordance with the material specifications, except as required by this Subarticle. References to dimensions signify nominal values.

NG-2222 Plates

NG-2222.1 Number of Tension Test Coupons.

The number of tension test coupons required shall be in accordance with the material specification and SA-20,

Page 14

except that from carbon steel plates weighing 42,000 lb (20050 kg) and over and alloy steel plates weighing 40,000 lb (18140 kg) and over, two tension test coupons shall be taken, one representing the top end of the plate and one representing the bottom end of the plate.

NG-2222.2 Orientation and Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from a rolled surface and with the midlength of the specimen at least t from any heat treated edge, where t is the nominal thickness of the material.

NG-2222.3 Requirements for Separate Test Coupons.

Where a separate test coupon is used to represent the core support structure material, it shall be of sufficient size to ensure that the cooling rate of the region from which the test coupons are removed represents the cooling rate of the material at least $\frac{1}{4}t$ deep and t from any edge of the product. Unless cooling rates applicable to the bulk pieces or product are simulated in accordance with NG-2212.2(b), the dimensions of the coupon shall be not less than $3t \times 3t \times t$, where t is the nominal material thickness.

NG-2223 Forgings

NG-2223.1 Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from any surface and with the midlength of the specimens at least t from any second surface, where t is the maximum heat treated thickness. A thermal buffer as described in NG-2212.2(c) may be used to achieve these conditions, unless cooling rates applicable to the bulk forgings are simulated as otherwise provided in NG-2212.2.

NG-2223.2 Very Thick and Complex Forgings.

Test coupons for forgings which are both very thick and complex, such as contour nozzles, flanges, nozzles, and other complex forgings that are contour shaped or machined to essentially the finished product configuration prior to heat treatment, may be removed from prolongations or other stock provided on the product. The Certificate Holder shall specify the surfaces of the finished product subjected to high tensile stresses in service. The coupons shall be taken so that specimens shall have their longitudinal axes at a distance below the nearest heat treated surface, equivalent at least to the greatest distance that the indicated high tensile stress surface will be from the nearest surface during heat

treatment, and with the midlength of the specimens a minimum of twice this distance from a second heat treated surface. In any case, the longitudinal axes of the specimens shall not be nearer than $\frac{3}{4}$ in. (19 mm) to any heat treated surface and the midlength of the specimens shall be at least $1\frac{1}{2}$ in. (38 mm) from any second heat treated surface.

NG-2223.3 Coupons From Separately Produced Test Forgings.

Test coupons representing forgings from one heat and one heat treatment lot may be taken from a separately forged piece under the conditions given in (a) through (e) below.

(a) The separate test forging shall be of the same heat of material and shall be subjected to substantially the same reduction and working as the production forging it represents.

(b) The separate test forging shall be heat treated in the same furnace charge and under the same conditions as the production forging.

(c) The separate test forging shall be of the same nominal thickness as the production forging.

(d) Test coupons for simple forgings shall be taken so that specimens shall have their longitudinal axes at the region midway between midthickness and the surface and with the midlength of the specimens no nearer any heat treated edge than a distance equal to the forging thickness except when the thickness-to-length ratio of the production forging does not permit, in which case a production forging shall be used as the test forging and the midlength of the specimens shall be at the midlength of the test forging.

(e) Test coupons for complex forgings shall be taken in accordance with NG-2223.2.

NG-2224 Location of Coupons

(a) *Bars.* Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the outside or rolled surface and with the midlength of the specimens at least t from a heat treated end, where t is either the bar diameter or thickness.

(b) *Bolting Material.* For bolting material, the coupons shall be taken in conformance with the applicable material specification and with the midlength of the specimen at least one diameter or thickness from a heat treated end. When the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the quenched contour and size except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts.

Page 15

NG-2225 Tubular Products and Fittings

NG-2225.1 Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the inside or outside surface and with the midlength of the specimens at least t from a heat treated end, where t is the nominal wall thickness of the tubular product.

NG-2225.2 Separately Produced Coupons Representing Fittings.

Separately produced test coupons representing fittings may be used. When separately produced coupons are used, the requirements of NG-2223.3 shall be met.

NG-2226 Castings

NG-2226.1 Castings With 2 in. (51 mm) Maximum Thickness and Less.

For castings with a maximum thickness of 2 in. (51 mm) and less, the specimens shall be taken from either the standard separately cast coupons or the casting, in accordance with the material specification.

NG-2226.2 Castings With Thicknesses Exceeding 2 in. (51 mm) Maximum Thickness.

For castings exceeding a thickness of 2 in. (51 mm), the coupons shall be taken from the casting (or an extension of it) so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ of the maximum heat treated thickness from any surface and with the midlength of the specimens at least t from any second surface. A thermal buffer may be used [NG-2212.2 (c)].

NG-2226.3 Separately Cast Test Coupons for Castings With Thicknesses Exceeding 2 in (51 mm).

In lieu of the requirements of NG-2226.2, separately cast test coupons may be used under the conditions in (a), (b), and (c) below.

(a) The separate test coupon representing castings from one heat and one heat treatment lot shall be of the same heat of material and shall be subjected to substantially the same foundry practices as the production casting it represents.

(b) The separate test coupon shall be heat treated in the same furnace charge and under the same conditions as the production casting, unless cooling rates applicable to the bulk castings are simulated in accordance with NG-2212.2.

(c) The separate test coupon shall be not less than $3t \times 3t \times t$, where t equals the nominal thickness of the casting. Test specimens shall be taken with their longitudinal axes at the region midway between midthickness and the surface and with the midlength of the specimens no nearer any heat treated edge than a distance equal to the casting thickness.

NG-2226.4 Castings Machined or Cast to Finished Configuration Before Heat Treatment.

In lieu of the requirements of NG-2226.1, NG-2226.2, or NG-2226.3, test coupons may be removed from prolongations or other stock provided on the product. The coupons shall be taken so that specimens shall have their longitudinal axes at a distance below the nearest heat treated surface equivalent at least to the greatest distance that the indicated high tensile stress surface will be from the nearest outside surface during heat treatment and with the midlength of the specimens a minimum of twice this distance from a second heat treated surface. In any case, the longitudinal axes of the specimens shall be at least $\frac{3}{4}$ in. from any heat treated surface and the midlength of the specimens shall be at least $1\frac{1}{2}$ in. from any second heat treated surface. The Certificate Holder shall specify the surfaces of the finished product subjected to high tensile stresses in service.

NG-2300 FRACTURE TOUGHNESS REQUIREMENTS FOR MATERIAL

NG-2310 MATERIAL TO BE IMPACT TESTED

NG-2311 Components for Which Impact Testing of Material Is Required

(a) When the Design Specifications for core support structures require impact testing³ they shall be impact tested in accordance with the requirements of NG-2300, except that the following materials are not to be impact tested as a requirement of this Subsection:

- (1) material with a nominal section thickness of $\frac{5}{8}$ in. (16 mm) and less;
- (2) threaded structural fasteners, including studs, nuts, and bolts with a nominal size of 1 in. (25 mm) and less;
- (3) bars with a nominal cross-sectional area of 1 sq in. (645 mm²) and less;
- (4) all thicknesses of materials for pipe, tube, and fittings with a nominal pipe size 6 in. (DN 150) diameter and smaller;
- (5) austenitic stainless steels;
- (6) nonferrous material.

³ When impact testing is required, the methods of Appendix G may be used as an alternative procedure for assuring protection against nonductile fracture.

(b) Drop weight tests are not required for martensitic high alloy chromium (Series 4XX) steels and precipitation-hardening

steels listed in Tables 2A and 2B, Section II, Part D, Subpart 1. The other requirements of NG-2331 and NG-2332 apply for these steels. For nominal wall thickness greater than $2\frac{1}{2}$ in. (64 mm), the required C_v value shall be 40 mils (1.00 mm) lateral expansion.

NG-2320 IMPACT TEST PROCEDURES

NG-2321 Types of Tests

NG-2321.1 Drop Weight Tests.

The drop weight test, when required, shall be performed in accordance with ASTM E 208-91. Specimen types P-1, P-2, or P-3 may be used. The orientations and locations of all test specimens and the results of all tests performed to meet the requirements of NG-2330 shall be reported in the Certified Material Test Report.

NG-2321.2 Charpy V-Notch Tests.

The Charpy V-notch test (C_v), when required, shall be performed in accordance with SA-370. Specimens shall be in accordance with SA-370, Fig. 11, Type A. A test shall consist of a set of three full-size 10 mm × 10 mm specimens. The lateral expansion and absorbed energy, as applicable, and the test temperature, as well as the orientation and location of all tests performed to meet the requirements of NG-2330 shall be reported in the Certified Material Test Report.

NG-2322 Test Specimens

NG-2322.1 Location of Test Specimens.

Impact test specimens for quenched and tempered material shall be removed from the locations in each product form specified in NG-2220 for tensile test specimens. For material in other heat treated conditions, impact test specimens shall be removed from the locations specified for tensile specimens in the material specification. For all other material, the number of tests shall be in accordance with NG-2340. For threaded structural fasteners, the C_v impact test specimens shall be taken with the longitudinal axis of the specimen located at least one-half radius or 1 in. (25 mm) below the surface plus the machining allowance per side, whichever is less. The fracture plane of the specimens shall be at least one diameter or thickness from the heat treated end. When the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the quenched contour and size except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts.

NG-2322.2 Orientation of Impact Test Specimens

(a) Specimens for Charpy V-notch tests shall be oriented as follows.

(1) Specimens for forgings, other than threaded structural fasteners and bars, shall be oriented in a direction normal to the principal direction in which the material was worked. Specimens are neither required nor prohibited from the thickness direction.

(2) Specimens from material for pipe, tube, and fittings, except for those made from plate, shall be oriented in the axial direction.

(3) Specimens from threaded structural fastener material and bars shall be oriented in the axial direction.

(4) Specimens for all plate material, including those used for pipe, tube, and fittings, shall be oriented in a direction normal to the principal rolling direction, other than thickness direction.

(5) Specimens for cast material shall have their axes oriented the same as the axes of the tensile specimens (NG-2226).

(6) In cases (1) through (5) above, the length of the notch of the C_v specimen shall be normal to the surface of the material.

(b) Specimens for drop weight tests may have their axes oriented in any direction. The orientation used shall be reported in the Certified Material Test Report.

NG-2330 TEST REQUIREMENTS AND ACCEPTANCE STANDARDS⁴

NG-2331 Material for Core Support Structures Not Exceeding 2 in. Maximum Thickness

Material for core support structures (other than threaded structural fasteners) with nominal thickness 2 in. and less shall be tested as required in (a) and (b) below.

(a) Test three C_v specimens at a temperature lower than or equal to the lowest service temperature.⁵ All

4 In addition to providing a basis for acceptance standards for material, the test data are designated to be used as a basis for establishing in-service operation and for use in fracture prevention evaluation (Appendix G).

5 Lowest service temperature is the minimum temperature of the fluid around the component or, alternatively, the calculated volumetric average metal temperature expected during normal operation whenever the pressure within the reactor vessel exceeds 20% of the preoperational system hydrostatic test pressure.

Page 17

three specimens shall meet the requirements of Table NG-2331(a)-1.

**TABLE NG-2331(a)-1
REQUIRED C_v VALUES FOR CORE
STRUCTURE MATERIAL WITH 2 in. MAXIMUM
THICKNESS (OTHER THAN THREADED
STRUCTURAL FASTENERS)**

Nominal Wall Thickness, in.	Lateral Expansion, mils
$\frac{5}{8}$ or less	No test required
Over $\frac{5}{8}$ to $\frac{3}{4}$, incl.	20
Over $\frac{3}{4}$ to $1\frac{1}{2}$, incl.	25
Over $1\frac{1}{2}$ to $2\frac{1}{2}$, incl.	40

TABLE NG-2331(a)-1 REQUIRED C_v VALUES FOR CORE STRUCTURE MATERIAL WITH 2 in. MAXIMUM THICKNESS (OTHER THAN THREADED STRUCTURAL FASTENERS)

(b) Apply the procedures of (a) above to:

(1) base material;

(2) the base material, the heat affected zone, and weld metal from the weld procedure qualification tests in accordance with NG-4330;

with NG-4330;

(3) the weld metal of NG-2431.

NG-2332 Material With Thickness Exceeding 2 in. (51 mm)

Material for core support structures (other than threaded structural fasteners) with nominal wall thickness over 2 in. shall meet the requirements of (a) through (d) below.

(a) Establish a reference temperature RT_{NDT} ; this shall be done as required in (1) through (5) below.

(1) Determine a temperature T_{NDT} which is at or above the nil-ductility transition temperature by drop weight tests.

(2) At a temperature not greater than $(T_{NDT} + 60^\circ\text{F})$, each specimen of the C_v test (NG-2321.2) shall exhibit at least 35 mils lateral expansion and not less than 50 ft-lb absorbed energy. Retesting in accordance with NG-2350 is permitted. When these requirements are met, T_{NDT} is the reference temperature RT_{NDT} .

(3) In the event that the requirements of Step (2) are not met, conduct additional C_v tests in groups of three specimens (NG-2321.2) to determine the temperature T_{C_v} at which they are met. In this case, the reference temperature $RT_{NDT} = T_{C_v} - 60^\circ\text{F}$. Thus, the reference temperature RT_{NDT} is the higher of T_{NDT} or $(T_{C_v} - 60^\circ\text{F})$.

TEXT

(4) When a C_v test has not been performed at $(T_{NDT} + 60^\circ\text{F})$ or when the C_v test at $(T_{NDT} + 60^\circ\text{F})$ does not exhibit a minimum of 50 ft-lb energy absorption and 35 mils lateral expansion, a temperature representing a minimum of 50 ft-lb energy absorption and 35 mils lateral expansion may be obtained from a full C_v impact curve developed from the minimum data points of all the C_v tests performed.

TABLE NG-2333-1 REQUIRED C_v VALUES FOR THREADED STRUCTURAL FASTENER MATERIAL

Nominal Diameter, in.	Lateral Expansion, mils	Absorbed Energy, ft-lb
1 or less	No test required	No test required
1 through 4	25	No requirements
Over 4	25	45

TABLE NG-2333-1 REQUIRED C_v VALUES FOR THREADED STRUCTURAL FASTENER MATERIAL

(5) The lowest service temperature shall be not lower than $RT_{NDT} + 100^\circ\text{F}$ unless a lower temperature is justified by using methods similar to those contained in G-2000.

(b) Apply the procedures of (a) above to:

(1) the base material;

(2) the base material, the heat affected zone, and weld metal from the weld procedure qualification tests in accordance with NG-4330;

(3) the weld metal of NG-2431.

(c) Product forms having dimensions which prohibit obtaining drop weight test specimens shall be tested in accordance with NG-2331.

(d) Consideration shall be given to the effects of irradiation on material toughness properties (such as core beltline region of reactor). The Design Specifications shall include additional requirements, as necessary, to assure adequate fracture toughness for the service lifetime of the core support structures. The toughness properties may be verified in service periodically by a material surveillance program using the methods of ASTM E 185-82 and the material conditions monitored by the in-service inspection requirements of Section XI.

NG-2333 Threaded Structural Fasteners

For threaded structural fastener material, including studs and nuts, test three C_v specimens at a temperature no higher than the preload temperature or the lowest service temperature, whichever is the lesser. All three specimens shall meet the requirements of Table NG-2333-1.

Page 18

NG-2340 NUMBER OF IMPACT TESTS REQUIRED

NG-2341 Plates

One test shall be made from each plate as heat treated. Where plates are furnished in the nonheat-treated condition and qualified by heat treated test specimens, one test shall be made for each plate as-rolled. The term *as-rolled* refers to the plate rolled from a slab or directly from an ingot, not to its heat treated condition.

NG-2342 Forgings and Castings

(a) Where the weight of an individual forging or casting is less than 1000 lb (454 kg), one test shall be made to represent each heat in each heat treatment lot.

(b) When heat treatment is performed in a continuous type furnace with suitable temperature controls and equipped with recording pyrometers so that complete heat treatment records are available, a heat treatment charge shall be considered as the lesser of a continuous run not exceeding 8 hr duration or a total weight, so treated, not exceeding 2000 lb (907 kg).

(c) One test shall be made for each forging or casting of 1000 lb to 10,000 lb (454 kg to 4540 kg) in weight.

(d) As an alternative to (c) above, a separate test forging or casting may be used to represent forgings or castings of different sizes in one heat and heat treat lot, provided the test piece is a representation of the greatest thickness in the heat treat lot. In addition, test forgings shall have been subjected to substantially the same reduction and working as the forgings represented.

(e) Forgings or castings larger than 10,000 lb (4540 kg) shall have two tests per part for Charpy V-notch and one test for drop weights. The location of drop weight or C_v impact test specimens shall be selected so that an equal number of specimens is obtained from positions in the forging or casting 180 deg. apart.

(f) As an alternative to (e) for static castings, a separately cast test coupon (NG-2226.3) may be used; one test shall be made for Charpy V-notch and one test for drop weight.

NG-2343 Bars

One test shall be made for each diameter or size having a nominal cross-sectional area greater than 1 sq in. in each lot, where a lot is defined as one heat of material heat treated in one charge or as one continuous operation, not to exceed 6000 lb (2720 kg).

NG-2344 Tubular Products and Fittings

On products which are seamless or welded without filler metal, one test shall be made from each lot. On products which are welded with filler metal, one additional test with the specimens taken from the weld area shall also be made on each lot. A lot shall be defined as stated in the applicable material specification but in no case shall a lot consist of products from more than one heat of material and of more than one diameter, with the nominal thickness of any product included not exceeding that to be impact tested by more than $1/4$ in.; such a lot shall be in a single heat treatment load or in the same continuous run in a continuous furnace controlled within a 50°F range and equipped with recording pyrometers.

NG-2345 Threaded Structural Fastener Material

One test shall be made for each lot of material where a lot is defined as one heat of material heat treated in one charge or as one continuous operation, not to exceed in weight the following:

$1\frac{3}{4}$ in. diameter and less	1,500 lb
Over $1\frac{3}{4}$ in. to $2\frac{1}{2}$ in. diameter	3,000 lb
Over $2\frac{1}{2}$ in. to 5 in. diameter	6,000 lb
Over 5 in. diameter	10,000 lb

NG-2346 Test Definition

Unless otherwise stated in NG-2341 through NG-2345, the term *one test* is defined to include the combination of the drop weight test and the C_v test when RT_{NDT} is required (NG-2332) and only the C_v test when determination of RT_{NDT} is not required (NG-2331).

NG-2350 RETESTS

- (a) For C_v tests required by NG-2330, one retest at the same temperature may be conducted, provided:
- (1) the average value of the test results meets the minimum requirements;
 - (2) not more than one specimen per test is below the minimum requirements;
 - (3) the specimen not meeting the minimum requirements is not lower than 10 ft-lb (13.6 J) or 5 mils (0.13 mm) below the specified requirements.
- (b) A retest consists of two additional specimens taken as near as practicable to the failed specimens.
-

Page 19

For acceptance of the retest, both specimens shall meet the minimum requirements.

NG-2360 CALIBRATION OF INSTRUMENTS AND EQUIPMENT

Calibration of temperature instruments and C_v impact test machines used in impact testing shall be performed at the frequency specified in (a) or (b) below.

- (a) Temperature instruments used to control test temperature of specimens shall be calibrated and the results recorded to meet the requirements of NCA-3868 at least once in each 3 month interval.
- (b) C_v test machines shall be calibrated and the results recorded to meet the requirements of NCA-3868. The calibrations shall be performed at least once per year using methods outlined in ASTM E 23-72 and employing standard specimens obtained from the National Institute of Standards and Technology.

NG-2400 WELDING MATERIAL

NG-2410 GENERAL REQUIREMENTS

- (a) All welding material used in the construction and repair of components or material, except welding material used for hard surfacing, shall conform to the requirements of the material specification or to the requirements for other welding material as permitted in Section IX. In addition, welding material shall conform to the requirements stated in this Subarticle and to the rules covering identification in NG-2150.
- (b) The Certificate Holder shall provide the organization performing the testing with the information listed below, as applicable:
- (1) welding process;
 - (2) SFA Specification and classification;
 - (3) other identification if no SFA Specification applies;
 - (4) minimum tensile strength [NG-2431.1(e)] in either the as-welded or heat treated condition, or both [NG-2431.1(c)];
 - (5) drop weight test for material as-welded or heat treated, or both (NG-2332);
 - (6) Charpy V-notch test for material as-welded or heat treated, or both (NG-2331); the test temperature, and the lateral expansion or the absorbed energy, shall be provided;
 - (7) the preheat and interpass temperatures to be used during welding of the test coupon [NG-2431.1(c)];
 - (8) postweld heat treatment time, temperature range, and maximum cooling rate, if the production weld will be heat treated [NG-2431.1(c)];
 - (9) elements for which chemical analysis is required per the SFA Specification or WPS, and NG-2432;
 - (10) minimum delta ferrite (NG-2433).

NG-2420 REQUIRED TESTS

The required tests shall be conducted for each lot of covered, flux cored, or fabricated electrodes; for each heat of bare electrodes, rod, or wire for use with the OFW, GMAW, GTAW, PAW, and EGW (electro-gas welding) processes (Section IX, QW-492); for each heat of consumable inserts; for each combination of heat of bare electrodes and lot of submerged arc flux; for each combination of lot of fabricated electrodes and lot of submerged arc flux; for each combination of heat of bare electrodes or lot of fabricated electrodes and dry blend of supplementary powdered filler metal and lot of submerged arc flux; or for each combination of heat of bare electrodes and lot of electrosag flux. Tests performed on welding material in the qualification of weld procedures will satisfy the testing requirements for the lot, heat, or combination of heat and batch of welding material used, provided the tests required by NG-4000 and this Subarticle are made and the results conform to the requirements of this Article. The definitions in (a) through (h) below apply.

(a) A *dry batch of covering mixture* is defined as the quantity of dry covering ingredients mixed at one time in one mixing vessel; a dry batch may be used singly or may be subsequently subdivided into quantities to which the liquid binders may be added to produce a number of wet mixes [(c) below].

(b) A *dry blend* is defined as one or more dry batches mixed in a mixing vessel and combined proportionately to produce a uniformity of mixed ingredients equal to that obtained by mixing the same total amount of dry ingredients at one time in one mixing vessel.

(c) A *wet mix* is defined as the combination of a dry batch or dry blend [(a) and (b) above, respectively] and liquid binder ingredients at one time in one mixing vessel.

(d) A *lot of covered, flux cored, or fabricated electrodes* is defined as the quantity of electrodes produced from the same combination of heat of metal and dry batch, dry blend, or chemically controlled mixes of flux or core materials. Alternatively, a lot of covered, flux cored, or fabricated electrodes may be considered one type and size of electrode, produced in a continuous period, not to exceed 24 hr and not to exceed 100,000

Page 20

lb (45360 kg), from chemically controlled tube, wire, or strip and a dry batch, a dry blend, or chemically controlled mixes of flux, provided each container of welding materials is coded for identification and traceable to the production period, the shift, line, and the analysis range of both the mix and the rod, tube, or strip used to make the electrodes.

(1) *Chemically controlled tube, wire, or strip* is defined as consumable tube, wire, or strip material supplied on coils with a maximum of one splice per coil that has been chemically analyzed to assure that the material conforms to the electrode manufacturer's chemical control limits for the specific type of electrode. Both ends of each coil shall be chemically analyzed, except those coils which are splice free need only be analyzed on one end of the coil.

(2) *Chemically controlled mixes of flux* are defined as flux material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the electrode manufacturer's standard for each chemical element for that type electrode. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending.

(e) A *heat of bare electrode, rod, wire, or consumable insert* is defined as the material produced from the same melt of metal.

(f) Alternatively, for carbon and low alloy steel bare electrode, rod, wire, or consumable inserts for use with SAW, OFW, GMAW, GTAW, PAW, and EGW processes, a *heat* may be defined as either the material produced from the same melt of metal, or the material produced from one type and size of wire when produced in a continuous period, not to exceed 24 hr and not to exceed 100,000 lb (45360 kg), from chemically controlled wire, subject to requirements of (1), (2), and (3) below.

(1) For the chemical control of the product of the rod mill, coils shall be limited to a maximum of one splice prior to processing the wire. Chemical analysis shall be made from a sample taken from both ends of each coil of mill coiled rod furnished by mills permitting spliced coil practice of one splice maximum per coil. A chemical analysis need be taken from only one end of rod coils furnished by mills prohibiting spliced coil practice.

(2) Carbon, manganese, silicon, and other intentionally added elements shall be determined to identify the material to ensure that it conforms to the SFA or user's material specification.

(3) Each container of wire shall be coded for identification and traceability to the lot, production period, shift, line, and analysis of rod used to make the wire.

(g) A lot of submerged arc or electroslag flux is defined as the quantity of flux produced from the same combination of raw materials under one production schedule.

(h) A dry blend of supplementary powdered filler metal is defined as one or more mixes of material produced in a continuous period, not to exceed 24 hr and not to exceed 20,000 lb (9070 kg), from chemically controlled mixes of powdered filler metal, provided each container of powdered metal is coded for identification and traceable to the production period, the shift, and the mixing vessel. A chemically controlled mix of powdered filler metal is defined as powdered filler metal material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the powdered filler metal manufacturer's standard, for each chemical element, for that type of powdered filler metal. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending. The chemical analysis range of the supplemental powdered filler shall be the same as that of the welding electrode, and the ratio of powder to electrode used to make the test coupon shall be the maximum permitted for production welding.

NG-2430 WELD METAL TESTS

NG-2431 Mechanical Properties Test

Tensile and impact tests shall be made, in accordance with this paragraph, of welding material used to join P-Nos. 1, 3, 4, 5, 6, 7, 9, and 11 base materials in any combination, with the exceptions listed in (a) through (d) below:

- (a) austenitic stainless steel and nonferrous welding material used to join the listed P-Numbers;
- (b) consumable inserts (backing filler material);
- (c) welding material used for GTAW root deposits with a maximum of two layers;
- (d) welding material to be used for the welding of base material exempted from impact testing by NG-2300 shall likewise be exempted from the impact testing required by this paragraph.

NG-2431.1 General Test Requirements.

The welding test coupon shall be made in accordance with (a) through (f) below using each process with which the weld material will be used in production welding.

- (a) Test coupons shall be of sufficient size and thickness such that the test specimens required herein can be removed.
- (b) The weld metal to be tested for all processes except electroslag welding shall be deposited in such

Page 21

a manner as to eliminate substantially the influence of the base material on the results of the tests. Weld metal to be used with the electroslag process shall be deposited in such a manner as to conform to one of the applicable Welding Procedure Specifications (WPS) for production welding, Section IX, QW-201.1. The base material shall conform with the requirements of Section IX, QW-403.1 or QW-403.4, as applicable.

(c) The welding of the test coupon shall be performed within the range of preheat and interpass temperatures which will be used in production welding. Coupons shall be tested in the as-welded condition or they shall be tested in the applicable postweld heat treated condition when the production welds are to be postweld heat treated. The postweld heat treatment holding time⁶ shall be at least 80% of the maximum time to be applied to the weld metal in production application. The total time for postweld heat treatment of the test coupon may be applied in one heating cycle. The cooling rate from the postweld heat treatment temperature shall be of the same order as that applicable to the weld metal in the component. In addition, weld coupons for weld metal to be used with the electroslag process that are tested in the as-welded condition, or following a postweld heat treatment within the holding temperature ranges of Tables NG-4622.1-1 or NG-4622.4(c)-1, shall have a thickness within the range of 0.5 to 1.1 times the thickness of the welds to be made in production. Electroslag weld coupons to be tested following a postweld heat treatment which will include heating the coupon to a temperature above the "Holding Temperature Range" of Table NG-4622.1-1 for the type of material being tested shall have a thickness within the range of 0.9 to 1.1 times the thickness of the welds to be made in production.

- (d)

(d) Regardless of the welding process or welding material being tested, the tensile specimens, and the C_v impact specimens where required, shall be located and prepared in accordance with the requirements of SFA-5.1, Specification for Mild Steel Covered Electrodes. Drop weight impact test specimens, where required, shall be oriented so that the longitudinal axis is transverse to the weld with the notch in the weld face or in a plane parallel to the weld face. For impact specimen preparation and testing, the applicable parts of NG-2321.1 and NG-2321.2 shall apply. The longitudinal axis of the specimen shall be at a minimum depth of $1/4$ from a surface, where t is the thickness of the test weld.

6 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

(e) One all weld metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirements of the base material specification. When base materials of different specifications are to be welded, the tensile strength requirements shall conform to the specified minimum tensile strength requirements of either of the base material specifications.

(f) Impact specimens of the weld metal shall be tested where impact tests are required for either of the base materials of the production weld. The weld metal shall conform to the requirements of NG-2330 applicable to the base material. Where different requirements exist for the two base materials, the weld metal may conform to either of the two requirements.

NG-2431.2 Standard Test Requirements.

In lieu of the use of the General Test Requirements specified in NG-2431.1, tensile and impact tests may be made in accordance with this subparagraph where they are required for mild and low alloy steel covered electrodes. The material combinations to require weld material testing, as listed in NG-2431, shall apply for this Standard Test Requirements option. The limitations and testing under this Standard Test option shall be in accordance with (a) through (f) below.

(a) Testing to the requirements of this subparagraph shall be limited to electrode classifications included in Specification SFA-5.1 or SFA-5.5.

(b) The test assembly required by SFA-5.1 or SFA-5.5, as applicable, shall be used for test coupon preparation, except that it shall be increased in size to obtain the number of C_v specimens and the drop weight test specimens required by NG-2330, where applicable.

(c) The welding of the test coupon shall conform to the requirements of the SFA Specification for the classification of electrode being tested. Coupons shall be tested in the as-welded condition and also in the postweld heat treated condition. The postweld heat treatment temperatures shall be in accordance with Table NG-4622.1-1 for the applicable P-Number equivalent. The time at postweld heat treatment temperature shall be 8 hr (this qualifies postweld heat treatments of 10 hr or less). Where the postweld heat treatment of the production weld exceeds 10 hr or the PWHT temperature is other than that required above, the general test of NG-2431.1 shall be used.

(d) The tensile and C_v specimens shall be located and prepared in accordance with the requirements of SFA-5.1 or SFA-5.5, as applicable. Drop weight impact test specimens, where required, shall be located and oriented as specified in NG-2431.1(d).

**TABLE NG-2432.1-1
SAMPLING OF WELDING MATERIALS FOR
CHEMICAL ANALYSIS**

	GTAW/PAW	GMAW	All Other Processes
A-No. 8 filler metal	Filler metal or weld deposit	Weld deposit	Weld deposit
All other filler metal	Filler metal or weld deposit	Filler metal or weld deposit	Weld deposit

TABLE NG-2432.1-1 SAMPLING OF WELDING MATERIAL FOR CHEMICAL ANALYSIS

(e) One all weld metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirement of the SFA Specification for the applicable electrode classification.

(f) The requirements of NG-2431.1(f) shall be applicable to the impact testing of this option.

NG-2432 Chemical Analysis Test

Chemical analysis of filler metal or weld deposits shall be made in accordance with NG-2420 and as required by the following subparagraphs.

NG-2432.1 Test Method.

The chemical analysis test shall be performed in accordance with this subparagraph and Table NG-2432.1-1, and the results shall conform to NG-2432.2.

(a) A-No. 8 welding material to be used with GTAW and PAW processes and any other welding material to be used with any GTAW, PAW, or GMAW process shall have chemical analysis performed either on the filler metal or on a weld deposit made with the filler metal in accordance with (c) or (d) below.

(b) A-No. 8 welding material to be used with other than the GTAW and PAW processes and other welding material to be used with other than the GTAW, PAW, or GMAW process shall have chemical analysis performed on a weld deposit of the material or combination of materials being certified in accordance with (c) or (d) below. The removal of chemical analysis samples shall be from an undiluted weld deposit made in accordance with (c) below. As an alternative, the deposit shall be made in accordance with (d) below for material that will be used for corrosion resistant overlay cladding. Where the Welding Procedure Specification or the welding material specification specifies percentage

composition limits for analysis, it shall state that the specified limits apply for either the filler metal analysis or the undiluted weld deposit analysis or for *in situ* cladding deposit analysis in conformance with the above required certification testing.

(c) The preparation of samples for chemical analysis of undiluted weld deposits shall comply with the method given in the applicable SFA Specification. Where a weld deposit method is not provided by the SFA Specification, the sample shall be removed from a weld pad, groove, or other test weld⁷ made using the welding process that will be followed when the welding material or combination of welding materials being certified is consumed. The weld for A-No. 8 material to be used with the GMAW or EGW process shall be made using the shielding gas composition specified in the Welding Procedure Specifications that will be followed when the material is consumed. The test sample for ESW shall be removed from the weld metal of the Mechanical Properties Test coupon. Where a chemical analysis is required for a welding material which does not have a Mechanical Properties Test requirement, a chemical analysis test coupon shall be prepared as required by NG-2431.1(c), except that heat treatment of the coupon is not required and the weld coupon thickness requirements of NG-2431.1(c) do not apply.

(d) The alternative method provided in (b) above for the preparation of samples for chemical analysis of welding material to be used for corrosion-resistant overlay cladding shall require a test weld made in accordance with the essential variables of the Welding Procedure Specification that will be followed when the welding material is consumed. The test weld shall be made in conformance with the requirements of Section IX, QW-214.1. The removal of chemical analysis samples shall conform with QW-214.3 for the minimum thickness for which the Welding Procedure Specification is qualified.

NG-2432.2 Requirements for Chemical Analysis.

The chemical elements to be determined, the composition requirements of the weld metal, and the recording of results of the chemical analysis shall be in accordance with (a), (b), and (c) below.

(a) All welding material shall be analyzed for the elements listed in Table NG-2432.2-1 and for other elements specified either in the welding material specification referenced by the Welding Procedure Specification or in the Welding Procedure Specification.

⁷ The methods given in the Appendix of SFA 5.9, Specification for Corrosion-Resisting Chromium and Chromium-Nickel Steel Welding Rods and Bare Electrodes, shall be used to establish a welding and sampling method for the pad, groove, or other test weld to ensure that the weld deposit being sampled will be substantially free of base metal dilution.

these composition limits of the Welding Procedure Specification shall apply for acceptability.

TABLE NG-2432.2-1 WELDING MATERIAL CHEMICAL ANALYSIS

Carbon and low alloy materials	C, Cr, Mo, Ni, Mn, Si, P, S, V, Cu
Chromium and Cr-Ni stainless material	C, Cr, Mo, Ni, Mn, Si, P, S, V, Cb + Ta, Ti, cu
Nickel and Ni-alloy materials	C, Cr, Mo, Ni, Mn, Si, S, Cb + Ta, Cu, Fe, Co

TABLE NG-2432.2-1 WELDING MATERIAL CHEMICAL ANALYSIS

(b) The chemical composition of the weld metal or filler metal shall conform to the welding material specification for elements having specified percentage composition limits. Where the Welding Procedure Specification contains a modification of the composition limits of SFA or other referenced welding material specifications, or provides limits for additional elements,

(c) The results of the chemical analysis shall be reported in accordance with NCA-3867. Elements listed in Table NG-2432.2-1 but not specified in the welding material specification shall be reported for information only.

NG-2433 Delta Ferrite Determination

A determination of delta ferrite shall be performed on A-No. 8 weld material (Section IX, QW-442) backing filler metal (consumable inserts); bare electrode, rod, or wire filler metal; or weld metal, except that delta ferrite determinations are not required for SFA-5.4, Type 16-8-2, or A-No. 8 weld filler metal to be used for weld metal cladding.

NG-2433.1 Method.

Delta ferrite determinations of welding material, including consumable insert material, shall be made using a magnetic measuring instrument and weld deposits made in accordance with (b) below. Alternatively, the delta ferrite determinations for welding materials may be performed by the use of chemical analysis of NG-2432 in conjunction with Fig. NG-2433.1-1.

(a) Calibration of magnetic instruments shall conform to AWS A4.2-91.

(b) The weld deposit for magnetic delta ferrite determination shall be made in accordance with NG-2432.1(c).

(c) A minimum of six ferrite readings shall be taken on the surface of the weld deposit. The readings obtained shall be averaged to a single Ferrite Number (FN).

NG-2433.2 Acceptance Standards.

The minimum acceptable delta ferrite shall be 5FN. The results of the delta ferrite determination shall be included in the Certified Material Test Report of NG-2130 or NG-4120.

NG-2440 STORAGE AND HANDLING OF WELDING MATERIAL

Suitable storage and handling of electrodes, flux, and other welding material shall be maintained. Precautions shall be taken to minimize absorption of moisture by fluxes and cored, fabricated, and coated electrodes.

NG-2500 EXAMINATION AND REPAIR OF CORE SUPPORT STRUCTURE MATERIAL

NG-2510 EXAMINATION OF CORE SUPPORT STRUCTURE MATERIAL

Material for core support structures shall be examined by nondestructive methods applicable to the material and product form as required by the rules of this Subarticle.

NG-2520 EXAMINATION AFTER QUENCHING AND TEMPERING

Ferritic steel products that have their properties enhanced by quenching and tempering shall be examined by the methods specified in this Subarticle for each product form after the quenching and tempering phase of the heat treatment.

NG-2530 EXAMINATION AND REPAIR OF PLATE

NG-2531 Required Examination

All plates for core support structures greater than $\frac{3}{4}$ in. thickness shall be examined by the straight beam ultrasonic method in accordance with NG-2532.1.

NG-2532 Examination Procedures

NG-2532.1 Straight Beam Examination.

The requirements for straight beam examination shall be in accordance with SA-578, as shown in Section V, except that the extent of examination and the acceptance standards to be applied are given in (a) and (b) below.

GENERAL NOTES:

- (a) The actual nitrogen content is preferred. If this is not available, the following applicable nitrogen value shall be used:
 (1) GMAW welds-0.06%, except that when self shielding flux cored electrodes are used-0.12%.
 (2) Welds made using other processes-0.06%.
 (b) This diagram is identical to the WRC-1992 Diagram, except that the solidification mode lines have been removed for ease of use.

FIG. NG-2433.1-1 WELD METAL DELTA FERRITE CONTENT

FIG. NG-2433.1-1 WELD METAL DELTA FERRITE CONTENT

(a) *Extent of Examination.* 100% of one major plate surface shall be covered by moving the search unit in parallel

paths with not less than a 10% overlap.

(b) Acceptance Standards

(1) Any area where one or more imperfections produce a continuous total loss of back reflection accompanied by continuous indications on the same plane that cannot be encompassed within a circle whose diameter is 3 in. or one-half of the plate thickness, whichever is greater, is unacceptable.

(2) In addition, two or more imperfections smaller than described in (1) above shall be unacceptable unless separated by a minimum distance equal to the greatest diameter of the larger imperfection, or unless they may be collectively encompassed by the circle described in (1) above.

NG-2532.2 Angle Beam Examination.

The requirements for angle beam examination shall be in accordance with SA-577, Specification for Ultrasonic Shear Wave Inspection of Steel Plates, as shown in Section V, as supplemented by this subparagraph. The calibration notch, extent of examination, and the acceptance standards to be applied are given in (a) through (c) below.

(a) Calibration. Angle beam examination shall be calibrated from a notch.

(b) Extent of Examination. 100% of one major plate surface shall be covered by moving the search unit in parallel paths with not less than 10% overlap.

(c) Acceptance Standards. Material which shows one or more imperfections which produce indications exceeding in amplitude the indication from the calibration notch is unacceptable.

NG-2537 Time of Examination

Acceptance examinations shall be performed at the time of manufacture as required in (a) through (c) below.

(a) Ultrasonic examination shall be performed after rolling to size and after heat treatment, except postweld heat treatment.

(b) Radiographic examination of repair welds, when required, may be performed prior to any required postweld heat treatment.

(c) Magnetic particle or liquid penetrant examination of repair welds in ferritic material shall be performed after final heat treatment, except that the examination may be performed prior to postweld heat treatment of P-No. 1 material 2 in. and less nominal thickness. All repair welds in austenitic and nonferrous material may be liquid penetrant examined prior to any required postweld heat treatment.

NG-2538 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining provided the requirements of (a) through (d) below are met.

(a) The depression, after defect elimination, is blended uniformly into the surrounding surface with not less than a 3:1 taper.

(b) After defect elimination, the area is examined by the magnetic particle method in accordance with NG-2545 or the liquid penetrant method in accordance with NG-2546 to assure that the defect has been removed or reduced to an imperfection of an acceptable size.

(c) Areas ground to remove oxide scale or other mechanically caused impressions for appearance or to facilitate proper ultrasonic testing need not be examined by the magnetic particle or liquid penetrant test method.

(d) If the elimination of the defect reduces the thickness of the section below the minimum required to satisfy the rules of NG-3000, the product shall be repaired in accordance with NG-2539.

NG-2539 Repair by Welding

Material from which defects have been removed may be repaired by welding, provided the requirements of the following

subparagraphs are met. Prior approval of the Certificate Holder shall be obtained for any repair of plates to be used in the manufacture of core support structures.

NG-2539.1 Defect Removal.

The defect shall be removed or reduced to an imperfection of an acceptable size by suitable mechanical or thermal cutting or gouging methods and the cavity prepared for repair (NG-4211.1).

NG-2539.2 Qualification of Welding Procedures and Welders.

The welding procedure and welders or welding operators shall be qualified in accordance with NG-4000 and Section IX.

NG-2539.3 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

NG-2539.4 Examination of Repair Welds.

Each repair weld shall be examined by the magnetic particle method (NG-2545) or by the liquid penetrant method (NG-2546). In addition, when the depth of the repair cavity exceeds the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness, the repair weld shall be radiographed in accordance with NG-5000 and to the acceptance standards of NG-5320 or shall be ultrasonically

Page 26

examined after repair in accordance with NG-2532.2 or NG-2532.1.

NG-2539.5 Heat Treatment After Repairs.

The product shall be heat treated after repair in accordance with the heat treatment requirements of NG-4620.

NG-2539.6 Material Report Describing Defects and Repairs.

Each defect repair exceeding in depth the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness and, in addition, all repair welds exceeding an accumulated area of 20% of the area of the part or 15 sq in., whichever is less, shall be described in the Certified Material Test Report. The Certified Material Test Report for each piece shall include a chart which shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results, including radiographic film.

NG-2540 EXAMINATION AND REPAIR OF FORGINGS AND BARS

NG-2541 Required Examinations

(a) Forgings NG-2551 shall be examined by the ultrasonic method in accordance with NG-2542, except that forgings or sections of forgings which have coarse grains or configurations which do not yield meaningful examination results by ultrasonic methods shall be examined by radiographic methods in accordance with Section V, Article 2, and the acceptance standards of NG-5320. In addition, selected surfaces, as designated by the Certificate Holder, shall be liquid penetrant examined in accordance with NG-2546 or magnetic particle examined in accordance with NG-2545.

(b) Forged flanges and fittings, such as elbows, tees, and couplings, shall be examined in accordance with the requirements of NG-2550.

(c) Bar material used for threaded structural fasteners shall be examined in accordance with NG-2580.

NG-2542 Ultrasonic Examination

NG-2542.1 Examination Procedure.

All forgings in the rough forged or finished condition, and bars, shall be examined in accordance with one of the

following specifications: SA-745, Standard Practice for Ultrasonic Examination of Austenitic Steel Forgings; or SA-388, Recommended Practice for Ultrasonic Testing and Inspection of Heavy Steel Forgings, as shown in Section V, Article 23. Contact, immersion, or water column coupling is permissible. The techniques of (a) through (c) below are required, as applicable.

(a) All forgings and bars shall be examined by the ultrasonic method using the straight beam technique.

(b) Ring forgings and other hollow forgings shall, in addition, be examined using the angle beam technique in two circumferential directions, unless wall thickness or geometric configuration makes angle beam examination impractical.

(c) Forgings may be examined by the use of alternative ultrasonic methods which utilize distance amplitude corrections provided the acceptance standards are shown to be equivalent to those listed in NG-2542.2.

NG-2542.2 Acceptance Standards

(a) *Straight Beam General Rule.* A forging shall be unacceptable if the results of straight beam examinations show one or more reflectors which produce indications accompanied by a complete loss of back reflection not associated with or attributable to geometric configurations. Complete loss of back reflection is assumed when the back reflection falls below 5% of full calibration screen height.

(b) *Angle Beam Rule.* A forging shall be unacceptable if the results of angle beam examinations show one or more reflectors which produce indications exceeding in amplitude the indication from the appropriate calibration notches.

NG-2545 Magnetic Particle Examination

NG-2545.1 Examination Procedure.

The procedure for magnetic particle examination shall be in accordance with the methods of Section V, Article 7.

NG-2545.2 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant.

(b) Any indication in excess of the NG-2545.3 acceptance standards which is believed to be nonrelevant shall be reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular

Page 27

or elliptical with the length equal to or less than three times the width.

NG-2545.3 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following relevant indications are unacceptable:

(1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for material less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for material from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for material 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

NG-2546 Liquid Penetrant Examination

NG-2546.1 Examination Procedure.

The procedure for liquid penetrant examination shall be in accordance with the methods of Section V, Article 6.

NG-2546.2 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities such as may occur from machining marks or surface conditions may produce similar indications which are not relevant.

(b) Any indication in excess of the NG-2546.3 acceptance standards which is believed to be nonrelevant shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NG-2546.3 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following relevant indications are unacceptable:

(1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for material less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for material from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

NG-2547 Time of Examination

Acceptance examinations, including those for repair welds, shall be performed at the time of manufacture as required in (a) and (b) below.

(a) Ultrasonic examination may be performed at any time after forging, and the maximum practical volume shall be examined after final heat treatment, excluding postweld heat treatment.

(b) Radiographic examination of repair welds, if required, may be performed prior to any required postweld heat treatment.

NG-2548 Elimination of Surface Defects

Elimination of surface defects shall be made in accordance with NG-2538.

NG-2549 Repair by Welding

Repair by welding shall be in accordance with NG-2539, except that:

(a) the depth of repair that is permitted is not limited; and

(b) for ferritic steel forgings, the completed repair may be examined by the ultrasonic methods in accordance with the requirements of NG-2542 in lieu of radiography.

Page 28

NG-2550 EXAMINATION AND REPAIR OF SEAMLESS AND WELDED TUBULAR PRODUCTS AND FITTINGS

NG-2551 Required Examination

(a) The examination performed shall be practical and yield meaningful pertinent information for the product form being examined. Certain examination methods are ineffective for some material conditions and product configuration. Some examples are:

(1) it may not be practical or meaningful to examine irregular shapes such as welding flanges and fittings by ultrasonic methods;

(2) ultrasonic examination employing special techniques is required on coarse-grained austenitic stainless steel or coarse-grained nickel-base alloy materials.

(b) Welded tubular products and fittings (including flanges and fittings) made from plate material greater than $\frac{3}{4}$ in. in thickness shall be ultrasonically or radiographically examined in accordance with NG-2552 or NG-2553.

(c) All welds in welded tubular products and fittings (including flanges and fittings) shall be ultrasonically or radiographically examined in accordance with NG-2552 or NG-2553. In addition, all welds shall be magnetic particle or liquid penetrant examined on all accessible surfaces in accordance with NG-2555 or NG-2556.

(d) Wrought seamless tubular products and fittings (including flanges and fittings machined from forgings and bars) greater than $\frac{3}{8}$ in. thickness shall be ultrasonically or radiographically examined in accordance with NG-2552 or NG-2553.

NG-2552 Ultrasonic Examination

NG-2552.1 Examination Procedure.

The procedure for ultrasonic examination shall provide a sensitivity which will consistently detect defects that produce indications equal to and greater than the indication produced by standard defects included in the reference specimen specified in NG-2552.2. Products with defects that produce indications in excess of the indications produced by the standard defects in the reference specimens are unacceptable unless the defects are eliminated or repaired in accordance with NG-2558 or NG-2559, as applicable.

NG-2552.2 Reference Specimens

(a) The reference specimen shall be of the same nominal diameter and thickness and of the same nominal composition and heat treated condition as the product which is being examined. The standard defects shall be axial notches or grooves on the outside and the inside surfaces of the reference specimen and shall have a length of approximately 1 in. (25 mm) or less, a width not to exceed $\frac{1}{16}$ in. (1.6 mm), and a depth not greater than the larger of 0.004 in. (0.10 mm) or 5% of the nominal wall thickness. The reference specimen may be the product being examined.

(b) The reference specimen shall be long enough to simulate the handling of the product being examined through the examination equipment. When more than one standard defect is placed in a reference specimen, the defects shall be located so that indications from each defect are separate and distinct without mutual interference or amplification.

NG-2552.3 Checking and Calibration of Equipment.

The proper functioning of the examination equipment shall be checked and the equipment shall be calibrated by the use of the reference specimens, as a minimum:

- (a) at the beginning of each production run of a given size and thickness of a given material;
- (b) after each 4 hr or less during the production run;
- (c) at the end of the production run;
- (d) at any time that malfunctioning is suspected.

If during any check it is determined that the testing equipment is not functioning properly, all of the product that has been tested since the last valid equipment calibration shall be reexamined.

NG-2553 Radiographic Examination

The radiographic examination shall be performed in accordance with Section V, Article 2, as modified by NG-5111, using the acceptance requirements of NG-5320.

NG-2555 Magnetic Particle Examination

The magnetic particle examination shall be performed in accordance with the requirements of NG-2545.

NG-2556 Liquid Penetrant Examination

The liquid penetrant examination shall be performed in accordance with the requirements of NG-2546.

NG-2557 Time of Examination

Time of acceptance examination, including that of repair welds, shall be in accordance with NG-2537.

Page 29

NG-2558 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining provided the requirements of (a) through (c) below are met.

- (a) The depression, after defect elimination, is blended uniformly into the surrounding surface.
- (b) After defect elimination, the area is reexamined by the method which originally disclosed the defect to assure that the defect has been removed or reduced to an imperfection of acceptable size.
- (c) If the elimination of the defect reduces the thickness of the section below the minimum required to satisfy the rules of NG-3000, the product shall be repaired in accordance with NG-2559.

NG-2559 Repair by Welding

Repair welding of base material defects shall be in accordance with NG-2539. Repair welding of seam defects shall be made in accordance with NG-4450.

NG-2570 EXAMINATION AND REPAIR OF STATICALLY AND CENTRIFUGALLY CAST PRODUCTS

NG-2571 Required Examinations

NG-2571.1 General Requirements.

The portion of castings, as specified by the Design Specifications or drawings, used for core support structures shall be examined over the maximum feasible volume by radiographic methods, or ultrasonic methods, or a combination of both methods. Castings or sections of castings which have coarse grains or configurations which do not yield meaningful examination results by ultrasonic methods shall be examined by radiographic methods. In addition, the portion of castings used for core support structures shall be examined on accessible surfaces by either magnetic particle or liquid penetrant methods. Accessible machined surfaces, except threaded surfaces, of a cast product shall be examined by

either liquid penetrant or magnetic particle methods after machining.

NG-2571.2 Alternative General Requirements.

The portion of castings 2 in. (51 mm) thick and less, which are specified by the Design Specifications or drawings to be used for core support structures, may be utilized when the requirements of (a) through (d) below are met.

(a) The design stress intensity values in Tables 2A, 2B and 3, Section II, Part D, Subpart 1 are reduced by applying a quality factor of 0.75.

(b) A fatigue strength reduction factor of 2.0 is applied to the allowable S_a values when peak stresses are considered.

(c) The portions of castings used as core support structures are magnetic particle or liquid penetrant examined per NG-2575 or NG-2576 on all accessible as-cast or, if machined, machine-finished surfaces. The acceptance criteria of NG-2575 or NG-2576 shall be utilized except that no linear indications greater than $\frac{1}{16}$ in. are permitted.

(d) Five pilot castings⁸ made from a new or altered design of a production run⁹ shall be radiographically examined over the maximum feasible volume to the requirements of NG-2573.1. If all five pilot castings meet the radiographic acceptance criteria, a production run may be poured. The production run shall be examined using either of the sampling plans specified in (1) or (2) below. The five pilot castings, having passed examination, are not to be included in the following sampling examination programs.

(1) The production run shall be considered a single lot. Twenty castings shall be randomly selected from the production run and examined to the requirements of the pilot castings. The production run is accepted if all 20 castings meet the examination requirements and it is rejected if any one of the 20 castings does not meet the examination requirements. Acceptable castings may be retrieved from a rejected production run by examining all castings from that production run.

(2) The production run castings shall, in order of manufacture, be grouped into sublots with a maximum of 25 castings each. Five castings shall be randomly selected from each subplot and examined to the requirements of the pilot castings. The subplot is accepted if all five castings meet the examination requirements and it is rejected if any one of the five castings does not meet the examination requirements. In the event two sublots are rejected by the sampling examination, succeeding sublots shall have eight castings randomly selected for examination to the requirements of the pilot castings. In any event, acceptable castings may be retrieved from a rejected subplot by examining all castings from that subplot.

8 A pilot casting is a casting poured to a production run to prove the casting process. Pilot castings shall be made from the same pattern, poured of the same type or grade of material, and use the identical foundry procedure (risering, gating, pouring, and melting) as each casting in the production run.

9 A production run is a maximum of 100 castings made from the same pattern, poured of the same type or grade of material, and using the identical foundry procedure (risering, gating, pouring, and melting) as the pilot castings. All castings in a production run need not be made from the same heat of material.

Page 30

NG-2572 Ultrasonic Examination of Castings

The requirements for ultrasonic examination of statically and centrifugally cast products are given in the following subparagraphs.

NG-2572.1 Straight Beam Method.

When castings are to be examined ultrasonically, all sections, regardless of thickness, shall be examined in accordance with SA-609, Standard Method and Specification for Longitudinal Beam Ultrasonic Inspection of Carbon and Low Alloy Castings, as shown in Section V; however, supplementary angle beam examination in accordance with NG-2572.2 or radiographic examination in accordance with NG-2573 shall be performed in areas where a back reflection cannot be maintained during the straight beam examination, or where the angle between the two surfaces of the casting is more than 15 deg.

NG-2572.2 Angle Beam Method.

Examination shall be conducted in accordance with Section V, T-524 except that the acceptance standards in Section V do not apply.

NG-2572.3 Acceptance Standards

(a) The Quality Levels of SA-609 as shown in Section V shall apply for the casting thicknesses indicated:

- (1) Quality Level 1 for thicknesses up to 2 in. (51 mm).
- (2) Quality Level 3 for thicknesses 2 to 4 in. (51 mm to 102 mm).
- (3) Quality Level 4 for thicknesses greater than 4 in. (102 mm).

(b) In addition to the Quality Level requirements stated in (a) above, the requirements in (1) through (5) below shall apply for both straight beam and angle beam examination.

(1) Area imperfections producing indications exceeding the Amplitude Reference Line with any dimension longer than those specified in the following tabulation are unacceptable:

<u>UT Quality Level</u>	<u>Longest Dimension of Area¹⁻³</u>
1	1.5 in.
2	2.0 in.
3	2.5 in.
4	3.0 in.

TABLE

NOTES:

(1) The areas for the Ultrasonic Quality Levels in SA-609 as shown in Section V refer to the surface area on the casting over which a continuous indication exceeding the transfer-corrected distance-amplitude curve is maintained.

(2) Areas are to be measured from dimensions of the movement of the search unit, using the center of the search unit as the reference point.

(3) In certain castings, because of very long metal path distances or curvature of the examination surfaces, the surface area over which a given discontinuity is detected may be considerably larger or smaller than the actual area of the discontinuity in the casting; in such cases, other criteria which incorporate a consideration of beam angles or beam spread must be used for realistic evaluation of the discontinuity.

(2) Quality Level 1 shall apply for the volume of castings within 1 in. (25 mm) of the surface regardless of the overall thickness.

(3) Imperfections indicated to have a change in depth equal to or greater than one-half the wall thickness or 1 in., whichever is less, are unacceptable.

(4) Two or more imperfections in the same plane with indication amplitudes exceeding the Amplitude Reference Line and separated by a distance less than the longest dimension of the larger of the adjacent imperfections are unacceptable if they cannot be encompassed within an area less than that of the Quality Level specified in (1) above.

(5) Two or more imperfections greater than permitted for Quality Level 1 for castings less than 2 in. in thickness, greater than permitted for Quality Level 2 for thickness 2 in. through 4 in., and greater than permitted for Quality

Level 3 for thickness greater than 4 in., separated by a distance less than the longest dimension of the larger of the adjacent imperfections, are unacceptable if they cannot be encompassed in an area less than that of the Quality Level requirements stated in (a) above.

NG-2573 Radiographic Examination

NG-2573.1 Extent, Methods, and Acceptance Standards.

Radiographic examination, where required, shall be performed on castings used for core support structures. The radiographic methods shall be in accordance with ASTM E 94-77, Recommended Practice for Radiographic Testing, and ASTM E 142-77, Controlling Quality of Radiographic Testing, and shall meet the acceptance requirements of Severity Level 3 for Category A and B defects and Severity Level 2 for Category C defects of ASTM E 446-78,¹⁰ Reference Radiographs for Steel Castings Up To 2 in. In Thickness, ASTM E 186-75,¹⁰ Reference Radiographs for Heavy-Walled (2 to 4½ in.) Steel Castings, or ASTM E 280-75,¹⁰ Reference Radiographs for Heavy-Walled (4½ to 12 in.) Steel Castings, as applicable for the thickness being radiographed, except that Category D, E, F, or G defects

¹⁰ The reference radiographs accompanying previous editions of ASTM E 186, E 280, and E 446 may be used with later editions of the specification, provided the text of the specified edition is used.

Page 31

are not acceptable. ASTM E 280-75¹⁰ shall also apply for castings over 12 in. in thickness.

NG-2573.2 Procedure.

The supplemental requirements in (a) through (d) below apply to the radiographic methods specified by ASTM E 94-77 and E 142-77.

(a) Type 4 film is not permitted.

(b) For those areas where relatively uniform thicknesses occur, the minimum film density shall be 1.5 for single viewing and 2.0 for composite viewing of multiple film exposures; each film of a composite set shall have a minimum density of 1.0, and the maximum film density permitted shall be 4.0.

(c) For those sections where the thickness varies sufficiently to cause difficulty in meeting the density requirements with one penetrometer, two penetrameters shall be used representing the thinnest and the thickest section in the area to be interpreted. Densities at or between the densities on the penetrameters shall be considered acceptable, except that the minimum density of the penetrometer image shall be 1.3 for single film viewing and 2.0 for composite film viewing of multiple film exposures; each film of a composite set shall have a minimum density of 1.0.

(d) The radiographic quality level shall be 2-4T for section thicknesses up to and including ¾ in. (19 mm) and 2-2T for section thicknesses greater than ¾ in. (19 mm) Radiographic quality is defined in Note 2 of ASTM E 94-77.

NG-2573.3 Film Identification

(a) Location markers, such as lead numbers or letters, which shall appear as radiographic images on the film, shall be placed on the casting and not on the film or film holder. Their locations shall be permanently stamped on the surface of the casting being radiographed in a manner permitting the area of interest on a radiograph to be accurately located on the casting and providing evidence on the radiograph that the extent of coverage required by NG-2573.1 has been obtained. On castings or sections of castings where stamping is not feasible, the radiographic procedure shall so state.

(b) In addition, each film of a casting being radiographed shall be identified with radiographic images of:

(1) name or symbol of the Material Organization, Certificate Holder, or subcontractor;

(2) job or heat number.

(c) Repairs (R_1 , R_2 , etc.), if applicable, date of radiography, and other indications may be made by a film imprinter, permanent ink, or imaged lead numbers.

NG-2575 Magnetic Particle Examination

The magnetic particle examination, when required, shall be performed in accordance with the requirements of NG-2545.

NG-2576 Liquid Penetrant Examination

The liquid penetrant examination, when required, shall be performed in accordance with the requirements of NG-2546.

NG-2577 Time of Examination

Acceptance examinations, including those for weld repairs, shall be performed as stipulated in the following subparagraphs.

NG-2577.1 Ultrasonic Examination.

Ultrasonic examination, if required, shall be performed at the stage of manufacture as required for radiography.

NG-2577.2 Radiographic Examination

(a) Radiography shall be performed after final heat treatment as required by the material specification, except radiography may be performed prior to postweld heat treatment. The examination shall be performed at the stage of manufacture defined in this subparagraph.

(b) Castings prior to finish machining shall be radiographed at the limiting thicknesses stipulated in (1) through (4) below.

(1) For thicknesses less than 2 in. (51 mm), castings shall be radiographed within 50% of the finished thickness. The penetrometer shall be based on the final thickness.

(2) For thicknesses less than 6 in. (152 mm) but greater than 2 in. (51 mm), castings shall be radiographed within 20% of the finished thickness. The penetrometer shall be based on the final thickness.

(3) For thicknesses 6 in. (152 mm) and greater, castings shall be radiographed within 10% of the finished thickness. The penetrometer shall be based on the final thickness.

(4) Where casting practices for core support structure sections require thickness to exceed the finished machined thickness limits of (2) and (3) above, radiography of the as-cast thickness is acceptable provided the acceptance reference radiographs of the next lesser thickness are met in those areas; for example, if the section being radiographed exceeds $4\frac{1}{2}$ in. (114 mm), use ASTM E 186-75¹⁰ reference radiographs. The penetrometer shall be based on the thickness of the section being radiographed.

Page 32

NG-2577.3 Magnetic Particle or Liquid Penetrant Examination.

Magnetic particle or liquid penetrant examination shall be performed after the final heat treatment required by the material specification. Repair weld areas shall be examined after postweld heat treatment when a postweld heat treatment is performed, except that repair welds in P-No. 1 material, 2 in. (51 mm) nominal thickness and less, may be examined prior to postweld heat treatment. For cast products with machined surfaces, all accessible finished machined surfaces, except threaded surfaces, shall also be examined by magnetic particle or liquid penetrant methods.

NG-2578 Elimination of Surface Defects

Elimination of surface defects shall be in accordance with NG-2538.

NG-2579 Repair by Welding

The Material Organization may repair castings by welding after removing the material containing defects. The depth of the repair is not limited. A cored hole or access hole may be closed by the Material Organization by welding in accordance with the requirements of this paragraph, provided the hole is closed by filler metal only. If the hole is closed by welding in a metal insert, the welding shall be in accordance with the requirements of NG-4000 by a Certificate of Authorization Holder.

NG-2579.1 Defect Removal.

The defect shall be removed or reduced to an imperfection of an acceptable size by suitable mechanical or thermal cutting or gouging methods, and the cavity prepared for repair. When thermal cutting is performed, consideration shall be given to preheating the material.

NG-2579.2 Qualification of Welding Procedures and Welders.

The welding procedure and welders or welding operators shall be qualified in accordance with NG-4000 and Section IX.

NG-2579.3 Blending of Repaired Areas.

After welding, the surface shall be blended uniformly into the surrounding surface.

NG-2579.4 Examination of Repair Welds.

Each repair weld shall be examined by the magnetic particle method (NG-2545) or by the liquid penetrant method (NG-2546). In addition, repair welds in cavities the depth of which exceeds the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness shall be radiographed in accordance with NG-2573. The radiographic method and acceptance standards of NG-2573 shall apply except that weld slag, including elongated slag, shall be considered as inclusions under Category B of the applicable reference radiographs. The total area of all inclusions, including slag inclusions, shall not exceed the limits of the applicable severity level of Category B of the reference radiographs.

NG-2579.5 Heat Treatment After Weld Repair.

After repair, the casting shall be heat treated in accordance with NG-4620, except that the heating and cooling limitations of NG-4623 do not apply.

NG-2579.6 Material Report Describing Defects and Repairs.

Each repair weld exceeding in depth either $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness shall be described in the Certified Material Test Report. The Certified Material Test Report shall include a chart for each repaired casting which shows the location and size of the repaired cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results, including radiographic film.

NG-2580 EXAMINATION OF THREADED STRUCTURAL FASTENERS

NG-2581 Required Examinations

Threaded structural fasteners shall be visually examined in accordance with NG-2582. Externally threaded structural fasteners $\frac{3}{8}$ in. (10 mm) and greater and nuts greater than 1 in. shall be examined by either the magnetic particle or liquid penetrant method. In addition, nominal sizes greater than $\frac{1}{2}$ in. (13 mm) but not over 4 in. (102 mm) shall be examined by ultrasonic methods as required by NG-2584, and nominal sizes greater than 4 in. (102 mm) shall be examined by ultrasonic methods as required by NG-2585.

NG-2582 Visual Examination

Externally threaded structural fasteners less than $\frac{3}{8}$ in. (10 mm) and nuts 1 in. (25 mm) and smaller shall be visually examined in the areas of threads, shanks, and heads of final machined parts prior to plating or other surface protection type treatments. Harmful discontinuities such as laps, seams, or cracks that would be detrimental to the intended service are unacceptable.

NG-2583 Magnetic Particle or Liquid Penetrant Examination

Externally threaded structural fasteners $\frac{3}{8}$ in. (10 mm) and greater and nuts greater than 1 in. (25 mm) shall be examined by a magnetic particle method

(NG-2545) or a liquid penetrant method (NG-2546). Such examination shall be performed on the finished threaded structural fastener after threading and prior to plating or other surface protection type treatments. On threaded surfaces no relevant indications are permitted. Relevant indications include any linear indications or rounded indications greater than $\frac{1}{16}$ in. (1.6 mm). Indications, caused by a particular manufacturing method, that may appear to be relevant, such as the crest of rolled threads or root of cut threads, may be shown to be nonrelevant and acceptable by prior process qualification or destructive metallographic examination. On all other accessible surfaces, no linear indications or rounded indications greater than $\frac{1}{16}$ in. (1.6 mm) are permitted, except that linear axial indications the smaller of one diameter or 1 in. (25 mm) in length are permitted.

NG-2584 Ultrasonic Examination for Sizes Greater Than $\frac{1}{2}$ in. (13 mm)

All threaded structural fasteners greater than $\frac{1}{2}$ in. (13 mm) nominal bolt size shall be ultrasonically examined over the entire surface prior to threading, in accordance with the requirements of the following subparagraphs.

NG-2584.1 Ultrasonic Method.

Examination shall be carried out by the straight beam, radial scan method.

NG-2584.2 Examination Procedure.

Examination shall be performed at a nominal frequency of 2.25 MHz unless variables such as production material grain structure necessitate the use of a 1 MHz frequency in order to assure adequate penetration, with a search unit not to exceed 1 sq in. (645 mm²) area.

NG-2584.3 Calibration of Equipment.

Calibration sensitivity shall be established by adjustment of the instrument so that the first back reflection is 75%-90% of full screen height.

NG-2584.4 Acceptance Standards.

Any imperfection which causes an indication in excess of 20% of the height of the first back reflection or any imperfection which prevents the production of a first back reflection of 50% of the calibration amplitude is not acceptable.

NG-2585 Ultrasonic Examination for Sizes Over 4 in.

In addition to the requirements of NG-2584, all threaded structural fasteners over 4 in. nominal size shall be ultrasonically examined over an entire end surface before or after threading in accordance with the requirements of the following subparagraphs.

NG-2585.1 Ultrasonic Method.

Examination shall be carried out by the straight beam, longitudinal mode scan method.

NG-2585.2 Examination Procedure.

Examination shall be performed at a nominal frequency of 2.25 MHz unless variables such as production material grain structure necessitate the use of a 1 MHz frequency in order to assure adequate penetration with a search unit having a circular cross section with a diameter not less than $\frac{1}{2}$ in. (13 mm) nor more than $1\frac{1}{8}$ in. (29 mm)

NG-2585.3 Calibration of Equipment.

Calibration shall be established on a test bar of the same nominal composition and diameter as the production part and a minimum of one-half of the length. A $\frac{3}{8}$ in. (10 mm) diameter $\times$ 3 in. (76 mm) deep flat bottom hole shall be drilled in one end of the bar and plugged to full depth. A distance-amplitude correction curve shall be established by scanning

from both ends of the test bar.

NG-2585.4 Acceptance Standards.

Any imperfection which causes an indication in excess of 50% of that produced by the calibration hole in the reference specimen, as corrected by the distance-amplitude correction curve, is not acceptable.

NG-2586 Elimination of Surface Defects

Surface defects may be eliminated by grinding or machining, provided the final dimension of the affected portion meets the requirements of the design and the area is reexamined by the magnetic particle or liquid penetrant method in accordance with NG-2583.

NG-2600 MATERIAL ORGANIZATIONS' QUALITY SYSTEM PROGRAMS

NG-2610 DOCUMENTATION AND MAINTENANCE OF QUALITY SYSTEM PROGRAMS

(a) Except as provided in (b) below, Material Organizations shall have a Quality System Program or an Identification and Verification Program, as applicable, which meets the requirements of NCA-3800.

(b) The requirements of NCA-3862 shall be met as required by NG-2130. The other requirements of NCA-3800 need not be used by Material Organizations for small products, as defined in (c) below, and for material which is allowed by this Subsection to be furnished with a Certificate of Compliance. For these products, the Certificate Holder's Quality Assurance Program (NCA-4000) shall include measures to provide assurance

Page 34

that the material is furnished in accordance with the material specification and with the applicable special requirements of this Subsection.

(c) For the purpose of this paragraph, small products are defined as given in (1) through (5) below:

- (1) pipe, tube (except heat exchanger tube), pipe fittings, and flanges 2 in. nominal pipe size (DN 50) and less;
- (2) bolting material, including studs, nuts, and bolts of 1 in. (25 mm) nominal diameter and less;
- (3) bars with a nominal cross-sectional area of 1 sq in. (645 mm²) and less.

American Society Of Mechanical Engineers

SEC III D1 NG-3000

ARTICLE NG-3000 DESIGN

Page 35

NG-3100 GENERAL DESIGN

NG-3110 LOADING CRITERIA

NG-3111 Loading Conditions

The loadings that shall be taken into account in designing core support structures include, but are not limited to, those in (a) through (k) below:

- (a) pressure differences due to coolant flow;
- (b) weight of the core support structure;
- (c) superimposed loads such as those due to other structures, the reactor core, steam separating equipment, flow

distributors and baffles, thermal shields, and safety equipment;

- (d) earthquake loads or other loads which result from motion of the reactor vessel;
- (e) reactions from supports, restraints, or both;
- (f) loads due to temperature effects, thermal gradients and differential expansion, or both;
- (g) loads resulting from the impingement or flow of reactor coolant, or other contained or surrounding fluids;
- (h) transient pressure difference loads, such as those which result from rupture of the main coolant pipe;
- (i) vibratory loads;
- (j) loads resulting from the operation of machinery, such as snubbing of control rods;
- (k) handling loads experienced in preparation for or during refueling or in-service inspection.

NG-3112 Design Loadings

The Design Loadings are the pressure differences, temperatures, and various forces applicable to the design of core support structures as defined in the following subparagraphs.

NG-3112.1 Design Pressure Difference

(a) The specified internal and external Design Pressure Difference shall not be less than the maximum difference in pressure between the inside and outside of the core support structure which exists under the specified normal service conditions. It shall be used in the computations made to show compliance with the stress intensity limits of NG-3221, NG-3227.1, NG-3227.2, NG-3227.4, NG-3228.1, NG-3228.2, and NG-3231. The actual service pressure difference at the appropriate time shall be used in the computations made to show compliance with the stress intensity limits of NG-3222, NG-3228.3, and NG-3232. When the occurrence of different pressure differences during service can be predicted for different zones of a structure, the Design Pressure Difference of the different zones may be based on their predicted pressure difference.

(b) The Design Pressure Difference shall include allowances for pressure difference surges.

NG-3112.2 Design Temperature.

The Design Temperature shall be established in accordance with NCA-2142.1(b). It shall be used in computations involving the Design Pressure Difference and coincidental Design Mechanical Loads. The actual metal temperature at the point under consideration shall be used in all computations where the use of the actual service pressure difference is required.

(a) All temperatures referred to in this Subsection are the metal temperatures expressed in degrees Fahrenheit (°F), unless otherwise stated.

(b) Where a core support structure is heated by tracing, induction coils, jacketing, or internal heat generation, the effect of such heating shall be incorporated in the establishment of the Design Temperature.

NG-3112.3 Design Mechanical Loads.

The specific combinations and values of mechanical loadings which must be considered in conjunction with the Design Pressure Difference and Design Temperature in evaluating the requirements of NG-3221.1 and NG-3221.2 shall be those identified in the Design Specifications (NCA-3250) and designated as the Design Mechanical Loads in accordance with NCA-2142.1(c). The actual mechanical loads at the appropriate time shall be used in the computations made to show compliance with

Page 40

the stress intensity limits of NG-3222.2 and NG-3222.4. The requirements of (a), (b), and (c) below shall also apply.

(a) Impact forces caused by either external or internal conditions shall be considered.

(b) The effects of earthquake shall be considered in the design of core support structures. The loadings, movements, and number of cycles to be used in the analysis shall be part of the Design Specifications. The stresses resulting from these earthquake effects shall be included with pressure differences or other applied loads.

(c) Core support structures shall be arranged and supported so that vibration will be minimized.

NG-3112.4 Design Stress Intensity Values.

Design stress intensity values for materials are listed in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1. The material shall not be used at metal temperatures and Design Temperatures above those for which stress intensity values are listed. The values in the Table may be interpolated for intermediate temperatures.

NG-3113 Service Loadings

Each loading to which the structure may be subjected shall be classified in accordance with NCA-2142 and Service Limits [NCA-2142.4(b)] designated in the Design Specifications in such detail as will provide a complete basis for design, construction, and inspection in accordance with these rules.

NG-3120 SPECIAL CONSIDERATIONS

NG-3121 Corrosion

Material subject to thinning by corrosion, erosion, mechanical abrasion, or other environmental effects shall have provision made for these effects during the design or specified life of the structure by a suitable increase in or addition to the thickness of the base metal over that determined by the design formulas. Material added or included for these purposes need not be of the same thickness for all areas of the structure if different rates of attack are expected for the various areas. It should be noted that the tests on which the design fatigue curves (Figs. I-9.0) are based did not include tests in the presence of corrosive environments which might accelerate fatigue failure.

NG-3122 Cladding

The rules of this paragraph apply to the design analysis of clad structures constructed of material permitted in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1.

NG-3122.1 Primary Stresses.

No structural strength shall be attributed to the cladding in satisfying NG-3221.1 and NG-3221.3.

NG-3122.2 Design Dimensions.

The dimensions given in (a) and (b) below shall be used in the design of the component.

(a) For structures subjected to internal pressure difference, the inside diameter shall be taken at the nominal inner face of the cladding.

(b) For structures subjected to external pressure difference, the outside diameter shall be taken at the outer face of the base metal.

NG-3122.3 Secondary and Peak Stresses.

In satisfying NG-3222.2 and NG-3222.4(b), the presence of the cladding shall be considered with respect to both the thermal analysis and the stress analysis. The stresses in both materials shall be limited to the values specified in NG-3222.2 and NG-3222.4(b). However, when the cladding is of the integrally bonded type and the nominal thickness of the cladding is 10% or less of the total thickness of the structure, the presence of the cladding may be neglected.

NG-3122.4 Bearing Stresses.

In satisfying NG-3227.1, the presence of cladding shall be included.

NG-3123 Welds Between Dissimilar Metals

In satisfying the requirements of this Subarticle, caution should be exercised in design and construction involving dissimilar metals having different coefficients of thermal expansion in order to avoid difficulties in service.

NG-3124 Environmental Effects

Changes in material properties may occur due to environmental effects. In particular, fast (> 1 MeV) neutron irradiation above a certain level may result in significant increase in the brittle fracture transition temperature and deterioration in the resistance to fracture at temperatures above the transition range (upper shelf energy). Therefore, structural discontinuities in ferritic structures should preferably not be placed in regions of high neutron flux.

Page 41

NG-3130 GENERAL DESIGN RULES

NG-3131 Scope

Design rules generally applicable to core support structures are provided in the following paragraphs.

NG-3132 Reinforcement for Openings

The rules for reinforcing applicable to Class 1 vessels and piping may be used in the design of core support structures if stipulated in the Design Specifications.

NG-3133 External Pressure Difference

NG-3133.1 General.

Rules are given in this paragraph for determining the stresses under external pressure difference loading in spherical shells, cylindrical shells with or without stiffening rings, and tubular products consisting of pipes, tubes, and fittings. Charts for determining the stresses in shells, hemispherical heads, and tubular products are given in Appendix VII.

NG-3133.2 Nomenclature.

The symbols used in this paragraph are defined as follows:

A	= factor determined from Fig. G, Section II, Part D, Subpart 3 and used to enter the applicable material chart in Section II, Part D, Subpart 3. For the case of cylinders having D_o/T values less than 10, see NG-3133.3(b). Also, factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used in a stiffening ring, corresponding to the factor B and the design metal temperature for the shell under consideration.
A_s	= cross-sectional area of a stiffening ring, sq in.
B	= factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used in a shell or stiffening ring at the design metal temperature, psi
D_o	= outside diameter of the cylindrical shell course or tube under consideration, in.
E	= modulus of elasticity of material at Design Temperature, psi (for this value, see Table TM, Section II, Part D, Subpart 2. Use the curve with this value on the material/temperature line of the applicable chart in Section II, Part D, Subpart 3.

I	= available moment of inertia of the combined ring-shell section about its neutral axis, parallel to the axis of the shell, in. ⁴ The width of the shell which is taken as contributing to the combined moment of inertia shall not be greater than $1.10 \sqrt{D_o} \bar{T}_n$ and shall be taken as lying one-half on each side of the centroid of the ring. Portions of shell plates shall not be considered as contributing area to more than one stiffening ring.
I_s	= required moment of inertia of the combined ring-shell section about its neutral axis parallel to the axis of the shell, in. ⁴
L	= total length of a tube between tubesheets, or the design length of a cylindrical section, taken as the largest of the following: (1) the distance between head tangent lines plus one-third of the depth of each head if there are no stiffening rings (2) the greatest center-to-center distance between any two adjacent stiffening rings, or (3) the distance from the center of the first stiffening ring to the head tangent line plus one-third of the depth of the head, all measured parallel to the axis of the cylinder, in.
L_s	= one-half of the distance from the center line of the stiffening ring to the next line of support on one side, plus one-half of the center line distance to the next line of support on the other side of the stiffening ring, both measured parallel to the axis of the component, in. A line of support is: (1) a stiffening ring that meets the requirements of this paragraph (2) a circumferential line on a head at one-third the depth of the head from the head tangent line, or (3) a circumferential connection to a jacket for a jacketed section of a cylindrical shell
P	= external design pressure, psi (gage or absolute, required)
P_2	= allowable external pressure, psi (gage or absolute, as required)
R	= inside radius of spherical shell, in.
S	= the lesser of 1.5 times the stress intensity at design metal temperature from Tables 2A, 2B, and 4, Section II, Part D, Subpart 1 or 0.9 times the tabulated yield strength at design metal temperature from Tables Y-1, Section II, Part D, Subpart 2, psi
T	= minimum required thickness of cylindrical shell or tube, or spherical shell, in.
T_n	= nominal thickness used, less corrosion allowance, of a cylindrical shell or tube, in.

NG-3133.3 Cylindrical Shells and Tubular Products

(a) The minimum thickness of cylindrical shells or tubular products under external pressure difference having D_o/T values equal to or greater than 10 shall

Page 42

be determined by the procedure given in Steps 1 through 8.

Step 1: Assume a value for T . Determine the ratios L/D_o and D_o/T .

Step 2: Enter Fig. G, Section II, Part D, Subpart 3 at the value of L/D_o determined in Step 1. For values of L/D_o greater than 50, enter the chart at a value of L/D_o of 50. For values of L/D_o less than 0.05, enter the chart at a value of L/D_o of 0.05.

Step 3: Move horizontally to the line for the value of D_o/T determined in Step 1. Interpolation may be made for intermediate values of D_o/T . From this intersection move vertically downwards and read the value of factor A .

Step 4: Using the value of A calculated in Step 3, enter the applicable material chart in Section II, Part D, Subpart 3 for the material/temperature under consideration. Move vertically to an intersection with the material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value of A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material line, see Step 7.

Step 5: From the intersection obtained in Step 4 move horizontally to the right and read the value of B .

Step 6: Using this value of B , calculate the maximum allowable pressure difference P_a by the following formula:

$$P_a = \frac{4B}{3D_o/T}$$

Step 7: For values of A falling to the left of the applicable material/temperature line, the value of P_a can be calculated using the following formula:

$$P_a = \frac{2AE}{3(D_o/T)}$$

Step 8: Compare P_a with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

(b) The minimum thickness of cylindrical shells or tubular products under external pressure difference having D_o/T values less than 10 shall be determined by the procedure given in Steps 1 through 4.

Step 1: Using the same procedure as given in (a) above, obtain the value of B . For values of D_o/T less than 4, the value of factor A can be calculated using the following formula:

$$A = \frac{1.1}{(D_o/T)^2}$$

For values of A greater than 0.10 use a value of 0.10.

Step 2: Using the value of B obtained in Step 1, calculate a value P_{a1} using the following formula:

$$P_{a1} = \left[\frac{2.167}{(D_o/T)} - 0.0833 \right] B$$

Step 3: Calculate a value P_{a2} using the following formula:

$$P_{a2} = \frac{2S}{D_o/T} \left[1 - \frac{1}{D_o/T} \right]$$

Step 4: The smaller of the values of P_{a1} calculated in Step 2 or P_{a2} calculated in Step 3 shall be used for the maximum allowable external pressure P_a . Compare P_a with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

NG-3133.4 Spherical Shells.

The minimum required thickness of a spherical shell under external pressure, either seamless or of built-up construction with butt joints, shall be determined by the procedure given in Steps 1 through 6.

Step 1: Assume a value for T and calculate the value of factor A using the following formula:

$$A = \frac{0.125}{(R/T)}$$

Step 2: Using the value of A calculated in Step 1, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection

Page 43

with the material/temperature line for the design temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value at A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values at A falling to the left of the material/temperature line, see Step 5.

Step 3: From the intersection obtained in Step 2, move horizontally to the right and read the value of factor B .

Step 4: Using the value of B obtained in Step 3, calculate the value of the maximum allowable external pressure P_a using the following formula:

$$P_a = \frac{B}{(R/T)}$$

Step 5: For values of A falling to the left of the applicable material/temperature line for the Design Temperature, the value of P_a can be calculated using the following formula:

$$P_a = \frac{0.0625 E}{(R/T)^2}$$

Step 6: Compare P_a obtained in Steps 4 or 5 with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

NG-3133.5 Stiffening Rings for Cylindrical Shells

(a) The required moment of inertia of the combined ring-shell section is given by the formula:

$$I_s = \frac{D_o^2 L_s (T + A_s / L_s) A}{10.9}$$

The available moment of inertia I for a stiffening ring shall be determined by the procedure given in Steps 1 through 6.

Step 1: Assuming that the shell has been designed and D_o , L_s , and T_n are known, select a member to be used for the stiffening ring and determine its area A_s and the value of I defined in NG-3133.2. Then calculate B by the formula:

$$B = \frac{3}{4} \left[\frac{PD_o}{T_n + A_s / L_s} \right]$$

Step 2: Enter the right-hand side of the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration at the value of B determined in Step 1. If different materials are used for the shell and stiffening ring, then use the material chart resulting in the larger value for factor A in Step 4 or 5 below.

Step 3: Move horizontally to the left to the material/temperature line for the design metal temperature. For values of B falling below the left end of the material/temperature line, see Step 5.

Step 4: Move vertically to the bottom of the chart and read the value of A .

Step 5: For values of B falling below the left end of the material/temperature line for the Design Temperature, the value of A can be calculated using the following formula:

$$A = 2B/E$$

Step 6: If the required I_s is greater than the computed moment of inertia I for the combined ring-shell section selected in Step 1, a new section with a larger moment of inertia must be selected and a new I_s determined. If the required I_s is smaller than the computed I for the section selected in Step 1, that section should be satisfactory.

(b) Stiffening rings may be attached to either the outside or the inside of the component by continuous welding.

NG-3133.6 Cylinders Under Axial Compression.

The maximum allowable compressive stress to be used in the design of cylindrical shells and tubular products subjected to loadings that produce longitudinal compressive stresses in the shell or wall shall be the lesser of the values given in (a) or (b) below:

(a) the S_m value for the applicable material at Design Temperature given in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1;

(b) the value of the factor B determined from the applicable chart contained in Section II, Part D, Subpart 3, using the following definitions for the symbols on the charts:

T = minimum required thickness of the shell or tubular product, exclusive of the corrosion allowance, in.

R = inside radius of the cylindrical shell or tubular product, in.

The value of B shall be determined from the applicable chart contained in Section II, Part D, Subpart 3 in the manner given in Steps 1 through 5.

Step 1: Using the selected values of T and R , calculate the value of factor A using the following formula:

$$A = 0.125/(R/T)$$

Step 2: Using the value of A calculated in Step 1, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value at A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material/temperature line, see Step 4.

Step 3: From the intersection obtained in Step 2, move horizontally to the right and read the value of factor B . This is the maximum allowable compressive stress for the values of T and R used in Step 1.

Step 4: For values of A falling to the left of the applicable material/temperature line, the value of B shall be calculated using the following formula:

$$B = AE/2$$

Step 5: Compare the value of B determined in Step 3 or 4 with the computed longitudinal compressive stress in the cylindrical shell or tube, using the selected values of T and R . If the value of B is smaller than the computed compressive stress, a greater value of T must be selected and the design procedure repeated until a value of B is obtained which is greater than the compressive stress computed for the loading on the cylindrical shell or tube.

NG-3200 DESIGN BY ANALYSIS

NG-3210 DESIGN CRITERIA

NG-3211 Requirements for Acceptability

The requirements for the acceptability of a design by analysis are those set forth in (a) through (d) below.

(a) The design shall be such that stress intensities will not exceed the limits of NG-3200 using the design stress intensity values S_m as tabulated in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1.

(b) The design details shall conform to the rules given in NG-3100 and NG-3350.

(c) For configurations where compressive stresses occur, in addition to the requirements in (a) and (b) above, the critical buckling stress shall be taken into account; see NG-3133. (For the special case of external pressure difference, see NG-3133.1. Where dynamic pressure differences are involved, the permissible external pressure difference shall satisfy the requirements of NG-3133 or be limited to 25% of the dynamic instability pressure difference for normal service conditions.)

(d) Protection against nonductile fracture shall be provided. An acceptable procedure for nonductile failure prevention is given in Appendix G.

NG-3212 Basis for Determining Stresses

The theory of failure used in the rules of this Subsection for combining stresses is the maximum shear stress theory. The maximum shear stress at a point is equal to one-half the difference between the algebraically largest and the algebraically smallest of the three principal stresses at the point.

NG-3213 Terms Relating to Stress Analysis

Terms used in this Subsection relating to stress analysis are defined in the following subparagraphs.

NG-3213.1 Stress Intensity.¹

Stress intensity is the equivalent intensity of combined stress, or, in short, the stress intensity is defined as twice the maximum shear stress. In other words, the stress intensity is the difference between the algebraically largest and the algebraically smallest principal stress at a given point. Tensile stresses are considered positive, and compressive stresses are considered negative.

¹ This definition of stress intensity is not related to the definition of stress intensity applied in the field of Fracture Mechanics.

Page 45

NG-3213.2 Gross Structural Discontinuity.

Gross structural discontinuity is a geometric or material discontinuity which affects the stress or strain distribution through the entire wall thickness of the shell-type member. Gross-discontinuity type stresses are those portions of the actual stress distributions that produce net bending and membrane force resultants when integrated through the wall thickness. Examples of gross structural discontinuities are head-to-shell and flange-to-shell junctions, nozzles, and junctions between shells of different diameters or thicknesses.

NG-3213.3 Local Structural Discontinuity.

Local structural discontinuity is a geometric or material discontinuity which affects the stress or strain distribution through a fractional part of the wall thickness. The stress distribution associated with a local discontinuity causes only very localized types of deformation or strain and has no significant effect on the shell-type discontinuity deformations. Examples are small fillet radii, small attachments, and partial penetration welds.

NG-3213.4 Normal Stress.

Normal stress is the component of stress normal to the plane of reference. This is also referred to as direct stress. Usually the distribution of normal stress is not uniform through the thickness of a part, so this stress is considered to be made up in turn of two components, one of which is uniformly distributed and equal to the average value of stress across the thickness under consideration, and the other of which varies from this average value with the location across the thickness.

NG-3213.5 Shear Stress.

Shear stress is the component of stress tangent to the plane of reference.

NG-3213.6 Membrane Stress.

Membrane stress is the component of normal stress which is uniformly distributed and equal to the average of stress across the thickness of the section under consideration.

NG-3213.7 Bending Stress.

Bending stress is the variable component of normal stress described in NG-3213.4. The variation may or may not be linear across the thickness.

NG-3213.8 Primary Stress.

Primary stress is any normal stress or a shear stress developed by an imposed loading which is necessary to satisfy the laws of equilibrium of external and internal forces and moments. The basic characteristic of a primary stress is that it is not self-limiting. Primary stresses which considerably exceed the yield strength will result in failure or, at least, in gross distortion. A thermal stress is not classified as a primary stress. A general primary membrane stress is one which is so distributed in the structure that no redistribution of load occurs as a result of yielding. Examples of primary stresses are:

(a) general membrane stress in a circular cylindrical or a spherical shell due to internal pressure difference or to distributed live loads;

(b) bending stress in the central portion of a flat head due to pressure difference.

NG-3213.9 Secondary Stress.

Secondary stress is a normal stress or a shear stress developed by the constraint of adjacent material or by self-constraint of the structure. The basic characteristic of a secondary stress is that it is self-limiting. Local yielding and minor distortions can satisfy the conditions which cause the stress to occur, and failure from one application of the stress is not to be expected. Examples of secondary stresses are:

(a) general thermal stress [NG-3213.12(a)];

(b) bending stress at a gross structural discontinuity.

NG-3213.10 Peak Stress.

Peak stress is that increment of stress which is additive to the primary plus secondary stresses by reason of local discontinuities or local thermal stress [NG-3213.12(b)], including the effects of stress concentrations. The basic characteristic of a peak stress is that it does not cause any noticeable distortion and is objectionable only as a possible source of a fatigue crack or a brittle fracture. A stress which is not highly localized falls into this category if it is of a type which cannot cause noticeable distortion. Examples of peak stresses are:

(a) the thermal stress in the austenitic steel cladding of a carbon steel component;

(b) certain thermal stresses which may cause fatigue but not distortion;

(c) the stress at a local structural discontinuity;

(d) surface stresses produced by thermal shock.

NG-3213.11 Load Stress.

Load stress is the stress resulting from the application of a load, such as pressure difference or the effects of gravity as distinguished from thermal stress.

NG-3213.12 Thermal Stress.

Thermal stress is a self-balancing stress produced by a nonuniform distribution of temperature or by differing thermal coefficients of expansion. Thermal stress is developed in a solid body whenever a volume of material is prevented from assuming the size and shape that it normally should under a change in temperature. For the purpose of establishing allowable stresses, two types of thermal stress are recognized, depending on the volume or area in which distortion takes place, as described in (a) and (b) below.

Page 46

(a) General thermal stress is associated with distortion of the structure in which it occurs. If a stress of this type, neglecting stress concentrations, exceeds twice the yield strength of the material, the elastic analysis may be invalid and successive thermal cycles may produce incremental distortion. Therefore this type is classified as secondary stress in Table NG-3217-1. Examples of general thermal stresses are:

(1) stress produced by an axial temperature distribution in a cylindrical shell;

(2) stress produced by the temperature difference between a nozzle and the shell to which it is attached;

(3) the equivalent linear stress² produced by the radial temperature distribution in a cylindrical shell.

(b) Local thermal stress is associated with almost complete suppression of the differential expansion and thus produces no significant distortion. Such stresses shall be considered only from the fatigue standpoint and are therefore classified as local stresses in Table NG-3217-1. In evaluating local thermal stresses the procedures of NG-3227.6(b) shall be used.

Examples of local thermal stresses are:

- (1) the stress in a small hot spot in a vessel wall;
- (2) the difference between the actual stress and the equivalent linear stress resulting from a radial temperature distribution in a cylindrical shell;
- (3) the thermal stress in a cladding material which has a coefficient of expansion different from that of the base metal.

NG-3213.13 Total Stress.

Total stress is the sum of the primary, secondary, and peak stress contributions. Recognition of each of the individual contributions is essential to establishment of appropriate stress limitations.

NG-3213.14 Operational Cycle.

Operational cycle is defined as the initiation and establishment of new conditions followed by a return to the conditions which prevailed at the beginning of the cycle. The types of operating conditions which may occur are further defined in NG-3113.

NG-3213.15 Stress Cycle.

Stress cycle is a condition in which the alternating stress difference [NG-3222.4(e)] goes from an initial value through an algebraic maximum value and an algebraic minimum value, then returns to the initial value. A single operational cycle may result in one or more stress cycles. Dynamic effects shall also be considered as stress cycles.

2 Equivalent linear stress is defined as the linear stress distribution which has the same net bending moment as the actual stress distribution.

NG-3213.16 Fatigue Strength Reduction Factor.

Fatigue strength reduction factor is a stress intensification factor which accounts for the effect of a local structural discontinuity (stress concentration) on the fatigue strength. In the absence of experimental data, the theoretical stress concentration factor may be used.

NG-3213.17 Shakedown.

Shakedown is the absence of a continuing cycle of plastic deformation. A structure shakes down if after a few cycles of load application, the deformation stabilizes and subsequent structural response is elastic, excluding creep effects.

NG-3213.18 Free End Displacement.

Free end displacement consists of the relative motions that would occur between an attachment and connected structure or equipment if the two members were separated. Examples of such motions are those that would occur because of relative thermal expansion of piping, equipment, and equipment supports or because of rotations imposed upon the equipment by sources other than the piping.

NG-3213.19 Expansion Stresses.

Expansion stresses are those stresses resulting from restraint of free end displacement of piping which may act as a core support structure.

NG-3213.20 Limit Analysis - Collapse Load.

The methods of limit analysis are used to compute the maximum load or combination of loads a structure made of ideally plastic (nonstrain-hardening) material can carry. The deformations of an ideally plastic structure increase without bound at this load, which is termed the *collapse load*. Among the methods used in limit analysis is a technique which assumes elastic, perfectly plastic, material behavior and a constant level of moment or force in those redundant structural elements in which membrane yield, plastic hinge, or critical buckling load has been reached. Any increase in load must be accompanied by a stable primary structure until a failure mechanism defined by the lower bound theorem of limit analysis is reached in the primary structure.

analysis is reached in the primary structure.

NG-3213.21 Collapse Load - Lower Bound.

If, for a given load, any system of stresses can be found which everywhere satisfies equilibrium and nowhere exceeds the material yield strength, the load is at or below the collapse load. This is the lower bound theorem of limit analysis which permits calculations of a lower bound to the collapse load.

NG-3213.22 Stress Ratio Method.

The methods of plastic analysis which utilize the stress ratio combinations are used to compute the maximum load a strain-hardened

Page 47

material can carry (A-9000). Stress ratio combinations are useful since the actual shape factor (function of cross section) and the type and magnitude of different stress fields may be considered in determining the load.

NG-3214 Stress Analysis

A detailed stress analysis of all major structural components shall be prepared in sufficient detail to show that each of the stress limitations of NG-3220 and NG-3230 is satisfied when the core support structure is subjected to the loadings of NG-3110. As an aid to the evaluation of these stresses, formulas and methods for the solution of certain recurring problems have been placed in Appendix A.

NG-3215 Derivation of Stress Intensities

One requirement for the acceptability of a design (NG-3210) is that the calculated stress intensities shall not exceed specified allowable limits. These limits differ depending on the stress category (primary, secondary, etc.) from which the stress intensity is derived. This paragraph describes the procedure for the calculation of the stress intensities which are subject to the specified limits. The steps in the procedure are stipulated in (a) through (e) below.

(a) At the point on the component which is being investigated, choose an orthogonal set of coordinates, such as tangential, longitudinal, and radial, and designate them by the subscripts t , l , and r . The stress components in these directions are then designated σ_t , σ_l , and σ_r for direct stresses and τ_{lt} , τ_{lr} , and τ_{rt} for shear stresses.

(b) Calculate the stress components for each type of loading to which the part will be subjected and assign each set of stress values to one or a group of the following categories:³

- (1) general primary membrane stress P_m (NG-3213.8)
- (2) primary bending stress P_b (NG-3213.7 and NG-3213.8)
- (3) expansion stress P_e (NG-3213.19)
- (4) secondary stress Q (NG-3213.9)
- (5) peak stress F (NG-3213.10)

(c) For each category, calculate the algebraic sum of the values of σ_i which result from the different types of loadings, and similarly for the other five stress components. Certain combinations of the categories must also be considered.

³ See Table NG-3217-1 and Fig. NG-3221-1, Note (4).

(d) Translate the stress components for the t , l , and r directions into principal stresses σ_1 , σ_2 , and σ_3 . In many pressure component calculations, the t , l , and r directions may be so chosen that the shear stress components are zero and σ_1 , σ_2 , and σ_3 are identical to σ_t , σ_l , and σ_r .

(e) Calculate the stress differences S_{12} , S_{23} , and S_{31} from the relations:

$$S_{12} = \sigma_1 - \sigma_2$$

$$S_{23} = \sigma_2 - \sigma_3$$

$$S_{31} = \sigma_3 - \sigma_1$$

The stress intensity S is the largest absolute value of S_{12} , S_{23} , and S_{31} .

NOTE: Membrane stress intensity is derived from the stress components averaged across the thickness of the section. The averaging shall be performed at the component level in (b) or (c) above.

NG-3216 Derivation of Stress Differences and Alternating Stress Intensities

If the specified operation of the structure does not meet the conditions of NG-3222.4(d), the ability of the structure to withstand the specified cyclic service without fatigue failure shall be determined as provided in NG-3222.4(e). The determination shall be made on the basis of the stresses at a point of the structure, and the allowable stress cycles shall be adequate for the specified service at every point. Only the stress differences due to cyclic service loadings as specified in the Design Specifications need be considered.

NG-3216.1 Constant Principal Stress Direction.

For any case in which the directions of the principal stresses at the point being considered do not change during the cycle, the steps stipulated in (a), (b), and (c) below shall be taken to determine the alternating stress intensity.

(a) *Principal Stresses.* Consider the values of the three principal stresses at the point versus time for the complete stress cycle, taking into account both the gross and local structural discontinuities and the thermal effects which vary during the cycle. These are designated as σ_1 , σ_2 , and σ_3 for later identification.

(b) *Stress Differences.* Determine the stress differences $S_{12} = \sigma_1 - \sigma_2$; $S_{23} = \sigma_2 - \sigma_3$; $S_{31} = \sigma_3 - \sigma_1$ versus time for the complete cycle. In what follows,

Page 48

the symbol S_{ij} is used to represent any one of these three stress differences.

(c) *Alternating Stress Intensity.* Determine the extremes of the range through which each stress difference S_{ij} fluctuates and find the absolute magnitude of this range for each S_{ij} . Call this magnitude S_{rij} and let $S_{alt\ ij} = 0.5S_{rij}$. The alternating stress intensity S_{alt} is the largest of the $S_{alt\ ij}$ values.

NG-3216.2 Varying Principal Stress Direction.

For any case in which the directions of the principal stresses at the point being considered do change during the stress cycle, it is necessary to use the more general procedure of (a) through (e) below.

(a) Consider the values of the six stress components σ_p , σ_{lp} , σ_{lp} , τ_{lp} , τ_{lp} , τ_{rt} versus time for the complete stress cycle, taking into account both the gross and local structural discontinuities and the thermal effects which vary during the cycle.

(b) Choose a point in time when the conditions are one of the extremes for the cycle (either maximum or minimum, algebraically) and identify the stress components at this time by the subscript i . In most cases it will be possible to choose at least one time during the cycle when the conditions are known to be extreme. In some cases it may be necessary to try different points in time to find the one which results in the largest value of alternating stress intensity.

(c) Subtract each of the six stress components σ_{lp} , σ_{lp} , etc., from the corresponding stress components σ_p , σ_p , etc., at each point in time during the cycle and call the resulting components σ'_p , σ'_p , etc.

(d) At each point in time during the cycle, calculate the principal stresses σ'_1 , σ'_2 , σ'_3 derived from the six stress components σ'_p , σ'_p , etc. Note that the directions of the principal stresses may change during the cycle but each principal stress retains its identity as it rotates.

(e) Determine the stress differences $S'_{12} = \sigma'_1 - \sigma'_2$, $S'_{23} = \sigma'_2 - \sigma'_3$, $S'_{31} = \sigma'_3 - \sigma'_1$ versus time for the complete cycle and find the largest absolute magnitude of any stress difference at any time. The alternating stress intensity S_{alt} is one-half of this magnitude.

NG-3217 Classification of Stress

Table NG-3217-1 provides assistance in the determination of the category to which a stress should be assigned.

NG-3220 STRESS LIMITS FOR OTHER THAN THREADED STRUCTURAL FASTENERS

NG-3221 Design Loadings

The stress intensity limits which must be satisfied for the Design Loadings (NG-3112) stated in the Design Specifications are the three limits of this paragraph and the special stress limits of NG-3227. The provisions of NG-3228 may provide relief from certain of these stress limits if plastic analysis techniques or tests are applied. The design stress intensity values S_m are given by NG-3229. The limits are summarized by Fig. NG-3221-1.

NG-3221.1 General Primary Membrane Stress Intensity.

(Derived from P_m in Fig. NG-3221-1.) This stress intensity is derived from the average value across the thickness of a section of the general primary stresses (see NG-3213.8) produced by design internal pressure difference and other specified Design Mechanical Loads, but excluding all secondary and peak stresses. Averaging is to be applied to the stress components prior to determination of the stress intensity values. The allowable value of the stress intensity is S_m at the Design Temperature.

NG-3221.2 Primary Membrane Plus Primary Bending Stress Intensity.

(Derived from $P_m + P_b$ in Fig. NG-3221-1.) This stress intensity is derived from the highest value across the thickness of a section of the general primary membrane stresses plus primary bending stresses produced by Design Pressure Difference and other specified Design Mechanical Loads, but excluding all secondary and peak stresses. The allowable value of this stress intensity is $1.5S_m$.

NG-3221.3 External Pressure Difference.

The provisions of NG-3133 apply.

NG-3222 Level A Service Limits

The Level A Service Limits must be satisfied for the Service Conditions [NCA-2142.2(a)] for which these limits are designated in the Design Specifications and are the four limits of this paragraph and NG-3227. The provisions of NG-3228 may provide relief from certain of these stress limits if plastic analysis techniques are applied. The design stress intensity values S_m are given by NG-3229. The limits are summarized by Fig. NG-3221-1.

NG-3222.1 Primary Membrane and Bending Stress Intensities.

The stresses due to primary loads presented

Page 49

during normal service must be computed and satisfy the limits of NG-3221. Pages 50-50

**TABLE NG-3217-1
CLASSIFICATION OF STRESS INTENSITIES FOR SOME TYPICAL CASES**

Core Support Structure	Location	Origin of Stress	Type of Stress	Classification	Discontinuity	
					Gross	Local
Cylindrical or spherical shell	Shell plate remote from discontinuities	Pressure difference	General membrane Gradient through plate thickness	P_m Q	No Yes	No No
		Axial thermal gradient	Membrane Bending	Q Q	Yes Yes	No No
	Junction with head or flange	Pressure difference	Membrane Bending	Q Q	Yes Yes	No No
Any shell or head	Any section across entire shell	External load or moment, or pressure difference	General membrane averaged across full section. Stress component perpendicular to cross section.	P_m	No	No
		External load or moment	Bending across full section. Stress component perpendicular to cross section.	P_m	No	No
	Near nozzle or other opening	External load or moment, or pressure difference	Membrane Bending Peak (fillet or corner)	Q Q F	Yes Yes Yes	No No Yes
	Any location	Temp. difference between shell and head	Membrane Bending	Q Q	Yes Yes	No No
Dished head or conical	Crown	Pressure difference	General membrane Bending	P_m P_b	No No	No No
	Knuckle of junction to shell	Pressure difference	Membrane Bending	$Q(1)$ Q	Yes Yes	No No
Flat head	Center region	Pressure difference	General membrane Bending	P_m P_b	No No	No No
	Junction to shell	Pressure difference	Membrane Bending	Q Q	Yes Yes	No No
Perforated head or shell	Typical ligament in a uniform pattern	Pressure difference or external load	General membrane (avg. through cross section) Bending (avg. through width of ligament, but gradient through plate) Peak	P_m P_b F	No No No	No No Yes
	Isolated or atypical ligament	Pressure difference	Membrane Bending Peak	Q F F	Yes Yes Yes	No Yes Yes

(Table NG-3217-1 continues on next page)

TABLE NG-3217-1 CLASSIFICATION OF STRESS INTENSITIES FOR SOME TYPICAL CASES

TABLE NG-3217-1 (CONT'D)
CLASSIFICATION OF STRESS INTENSITIES FOR SOME TYPICAL CASES

Core Support Structure	Location	Origin of Stress	Type of Stress	Classification	Discontinuity	
					Gross	Local
Nozzle	Cross section perpendicular to nozzle axis	Pressure difference or external load or moment	General membrane avg. across full section. Stress component perpendicular to section.	P_m	No	No
		External load or moment	Bending across nozzle section	P_m	No	No
	Nozzle wall	Pressure difference	General membrane	P_m	No	No
			Membrane	Q	Yes	No
			Bending	Q	Yes	No
			Peak	F	Yes	Yes
	Differential expansion	Membrane	Q	Yes	No	
		Bending	Q	Yes	No	
		Peak	F	Yes	Yes	
Cladding	Any	Differential expansion	Membrane Bending	F F	Yes Yes	Yes Yes
Any	Any	Radial thermal gradient through plate thickness(2)	Stress due to equivalent bending portion Stress due to nonlinear portion	$Q(3)$ F	Yes Yes	No Yes
Any	Any	Any	Stress concentration (notch effect)	F	Yes	Yes

NOTES:

- (1) Consideration must also be given to the possibility of wrinkling and excessive deformation in shells with large diameter-to-thickness ratio.
(2) Consider the possibility of thermal stress ratchet.
(3) Equivalent linear stress is defined as the linear stress distribution which has the same net bending moment as the actual stress distribution.

TABLE NG-3217-1 (CONT'D) CLASSIFICATION OF STRESS INTENSITIES FOR SOME TYPICAL CASES

4 The concept of stress differences discussed in NG-3216 is essential to determination to the maximum range, since algebraic signs must be retained in the computation. Note that this limitation on range is applicable to the entire history of normal Service Loadings, not just to the stresses resulting from each individual transient.

NG-3222.2 Primary Plus Secondary Stress Intensity.⁴

This stress intensity is derived from the highest value at any point across the thickness of a section of the general or local primary membrane stresses, plus primary bending stresses, plus secondary stresses, produced by the specified service pressure differences and other specified mechanical loads and by general thermal effects associated with normal service loadings. The effects of gross structural discontinuities but not of local structural discontinuities (stress concentrations) shall be included. The allowable value for the maximum range of this stress intensity is $3S_m$ [Fig. NG-3221-1, Note (1)], except for certain cyclic events which may exceed the $3S_m$ limit during the design life of the plant. For this exception, in lieu of meeting the $3S_m$ limit, an elastic-plastic fatigue analysis in accordance with NG-3228.3 may be performed to demonstrate that the cumulative fatigue usage attributable to the combination of these low cycle events plus all other cyclic events does not exceed a value of 1.0 when calculated in accordance with NG-3222.4.

NG-3222.3 Expansion Stress Intensity.⁴

This stress intensity is the highest value of stress, neglecting local structural discontinuities, produced at any point across the thickness of a section by the loadings which result from restraint of free end displacement and the effect of

anchor point motions. The allowable value of the maximum range of this stress intensity when combined with all other primary and secondary stress intensities is $3S_m$.

[98]
NG-3222.4 Analysis for Cyclic Operation

(a) *Suitability for Cyclic Condition.* The suitability of a structure for specified Service Loadings involving

cyclic application of loads and thermal conditions shall be determined by the methods described herein, except that the suitability of high strength threaded structural fasteners shall be determined by the methods of NG-3232.3(b) and the possibility of thermal stress ratchet shall be investigated in accordance with NG-3222.5. If the specified Service Loadings of the structure meet all of the conditions of (d) below, no analysis for cyclic service is required, and it may be assumed that the peak stress limit discussed in (b) below has been satisfied by compliance with the applicable requirements for material, design, fabrication, examination, and testing of this Subsection. If the Service Loadings do not meet all the conditions of (d) below, a fatigue analysis shall be made in accordance with (e) below or a fatigue test shall be made in accordance with II-1200. Pages 52-52

FIG. NG-3221-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITIES FOR SERVICE LEVELS A AND B

NOTES:

- (1) The symbols P_m , P_b , Q , and F do not represent single quantities, but rather sets of six quantities representing the six stress components σ_1 , σ_2 , σ_3 , τ_{12} , τ_{13} , and τ_{23} .
- (2) For configurations where compressive stresses occur, the stress limits shall be reviewed to take into account critical buckling stresses [NG-3211(c)].
- (3) When loads are transiently applied, consideration should be given to the use of dynamic load amplification.
- (4) The stresses in Category Q are those parts of the total stress which are produced by thermal gradients, structural discontinuities, etc., and do not include primary stresses which may also exist at the same point. It should be noted, however, that a detailed stress analysis frequently gives the combination of primary and secondary stresses directly and, when appropriate, this calculated value represents the total of $P_m + P_b + Q$, and not Q alone. Similarly, if the stress in Category F is produced by a stress concentration, the quantity F is the additional stress produced by the notch, over and above the nominal stress. For example, if a plate has a nominal stress intensity, $P_m = S$, $P_b = 0$, $Q = 0$, and a notch with a stress concentration K is introduced, then $F = P_m(K - 1)$ and the peak stress intensity equals $P_m + P_m(K - 1) = KP_m$.
- (5) The triaxial stresses represent the algebraic sum of the three primary principal stresses ($\sigma_1 + \sigma_2 + \sigma_3$) for the combination of stress components. Where uniform tension loading is present, triaxial stresses are limited to $4S_m$.
- (6) This limitation applies to the range of stress intensity. When the secondary stress is due to a temperature excursion at the point at which the stresses are being analyzed, the value of S_m shall be taken as the average of the S_m values tabulated in Tables 2A, 2B and 4, Section II, Part D, Subpart 1 for the highest and the lowest temperature of the metal during the transient. When part or all of the secondary stress is due to mechanical load, the value of S_m shall be taken as the S_m value for the highest temperature of the metal during the transient.
- (7) S_e is obtained from the fatigue curves, Figs. I-9.0. The allowable stress intensity for the full range of fluctuation is $2S_e$.
- (8) Values of S_{sh} , calculated on an elastic basis, shall not exceed the S_e value associated with 10 cycles when using the fatigue curves of Figs. I-9.0.
- (9) L_L = lower bound limit load with yield point equal to $1.5 S_m$ (where S_m is the value of allowable stress intensity at temperature as contained in Tables 2A, 2B and 4, Section II, Part D, Subpart 1. The lower bound limit load is here defined as that produced from the analysis of an ideally plastic (nonstrain-hardening) material where deformations increase with no further increase in applied load. The lower bound load is one in which the material everywhere satisfies equilibrium and nowhere exceeds the defined material yield strength using either a shear theory or a strain energy of distortion theory to relate multiaxial yielding to the uniaxial case.
- (10) S_s denotes the structural action of shakedown load as defined in NG-3213.17, calculated on a plastic basis as applied to a specific location on the structure.
- (11) L_s is defined in NG-3228.4.

FIG. NG-3221.1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITIES
FOR SERVICE LEVELS A AND B (CONT'D)

FIG. NG-3221-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITIES FOR SERVICE LEVELS A AND B (CONT'D)

(b) *Peak Stress Intensity.* This stress intensity is derived from the highest value at any point across the thickness of a section of all primary, secondary, and peak stresses produced by specified service pressure differences and other mechanical loads, and by general and local thermal effects associated with normal Service Conditions and including the effects of gross and local structural discontinuities.

(c) *Conditions and Procedures.* The conditions and procedures of NG-3222.4 are based on a comparison of peak stresses with strain cycling fatigue data. The strain cycling fatigue data are represented by design fatigue strength curves of Figs. I-9.0. These curves show the allowable amplitude S_a of the alternating stress intensity component (one-half of the alternating stress intensity range) plotted against the number of cycles. This stress intensity amplitude is calculated on the assumption of elastic behavior and, hence, has the dimensions of stress, but it does not represent a real stress when the elastic range is exceeded. The fatigue

curves are obtained from uniaxial strain cycling data in which the imposed strains have been multiplied by the elastic modulus and a design margin has been provided so as to make the calculated stress intensity amplitude and the allowable stress intensity amplitude directly comparable. As an exception to the use of strain controlled test data, Fig.

I-9.2.2, Curves B and C, are based on load controlled fatigue data. The curves have been adjusted, where necessary, to include the maximum effects of mean stress, which is the condition where the stress fluctuates about a mean value which is different from zero. As a consequence of this procedure, it is essential that the requirements of (b) above be satisfied at all times with transient stresses included, and that the calculated value of the alternating stress intensity be proportional to the actual strain amplitude. To evaluate the effect of alternating stresses of varying amplitudes, a linear damage relation is assumed in (e)(4) below.

(d) Components Not Requiring Analysis for Cyclic Service. An analysis for cyclic service is not required, and it may be assumed that the peak stress limit discussed in (b) above has been satisfied for a structure by compliance with the applicable requirements for material, design, fabrication, examination, and testing of this Subsection, provided the specified Service⁵ Loadings of the structure or portion thereof meets all the conditions stipulated in (1) through (4) below.

(1) Temperature Difference - Startup and Shutdown. The temperature difference in degrees Fahrenheit between any two adjacent points⁶ of the structure during normal service does not exceed $S_a/(2E\alpha)$, where S_a is the value obtained from the applicable design fatigue curves for the specified number of startup-shutdown cycles, α is the value of the instantaneous coefficient of thermal expansion at the mean value of the temperatures at the two points as given by Table TE, Section II, Part D, Subpart 2, and E is taken from Table TM, Section II, Part D, Subpart 2 at the mean value of the temperature at the two points.

5 As stated in NG-3223, for structures operating within the temperature limits of this Subsection, Service Loadings for which Level B Limits are designated must be considered as though Level A Limits were designated in evaluating exemptions from fatigue analysis.

6 Adjacent points are defined as points which are spaced less than the distance $(2\sqrt{Rt})$ from each other, where R and t are the mean radius and thickness, respectively, of the shell of revolution. In configurations other than a shell of revolution, either the allowable distance between adjacent points must be determined in appropriate configurations or a fatigue analysis shall be accomplished.

(2) Temperature Difference - Normal Service. The temperature difference in degrees Fahrenheit between any two adjacent points⁶ does not change⁷ during normal service by more than the quantity $S_a/(2E\alpha)$, where S_a is the value obtained from the applicable design fatigue curve of Figs. I-9.0 for the total specified number of significant temperature difference fluctuations. A temperature difference fluctuation shall be considered to be significant if its total algebraic range exceeds the quantity $S/2E\alpha$, where S is defined as follows.

(a) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_a obtained from the applicable design fatigue curve for 10^6 cycles.

(b) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_a obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(3) Temperature Difference - Dissimilar Materials. For structures fabricated from materials of differing moduli of elasticity and coefficients of thermal expansion or both, the total algebraic range of temperature fluctuation in degrees Fahrenheit experienced by the component during normal service does not exceed the magnitude $S_a/2(E_1\alpha_1 - E_2\alpha_2)$, where S_a is the value obtained from the applicable design fatigue curve for the total specified number of significant temperature fluctuations, E_1 and E_2 are the moduli of elasticity, and α_1 and α_2 are the values of the instantaneous coefficients of thermal expansion at the mean temperature value involved for the two materials of construction (Tables TE and TM, Section II, Part D, Subpart 1). A temperature fluctuation shall be considered to be significant if its total excursion exceeds the quantity $S/2(E_1\alpha_1 - E_2\alpha_2)$, where S is defined as follows:

(a) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_a obtained from the applicable design fatigue curve for 10^6 cycles.

(b) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_a obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve. If the two materials used have different applicable design fatigue curves, the lower value of S_a shall be used in applying the rules of this paragraph.

7 The algebraic range of the difference shall be used.

(4) Mechanical Loads. The specified full range of mechanical loads, including pipe reactions and pressure differences, does not result in load stresses whose range exceeds the S_a value obtained from the applicable design

fatigue curve of Figs. I-9.0 for the total specified number of significant^a load fluctuations. If the total specified number of significant load fluctuations exceeds 10^6 , the S_a value at $N = 10^6$ may be used. A load fluctuation shall be considered to be significant if the

total excursion of load stress exceeds the value of S_a , where S is defined as follows.

(a) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_a obtained from the applicable design fatigue curve for 10^6 cycles.

(b) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_a obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(e) *Procedure for Analysis for Cyclic Loading.* If the specified service loadings for the structure do not meet the conditions of (d) above, the ability of the structure to withstand the specified cyclic service without fatigue failure shall be determined as provided herein. The determination shall be made on the basis of the stresses at a point and the allowable stress cycles shall be adequate for the specified Service Loadings at every point. Only the stresses due to service cycles as specified in the Design Specifications need be considered. Compliance with these requirements means only that the structure is suitable from the standpoint of possible fatigue failure; complete suitability for the specified Service Loadings is also dependent on meeting the general stress limits of NG-3222 and any applicable special stress limits of NG-3227.

(1) *Stress Differences.* For each condition of normal service, determine the stress differences and the alternating stress intensity S_a in accordance with NG-3216.

(2) *Local Structural Discontinuities.* These effects shall be evaluated by the use of theoretical stress concentration factors for all conditions, except that experimentally determined fatigue strength reduction factors may be used when stated herein or when determined in accordance with the procedures of II-1600. Except for the case of cracklike defects and specific piping geometries for which specific values are given in NB-3680, no fatigue strength reduction factor greater than 5 need be used.

(3) *Design Fatigue Curves.* Figures I-9.0 contain the applicable fatigue design curves for the materials permitted by this Subsection. When more than one curve is presented for a given material, the applicability of each curve to material of various strength levels is identified. Linear interpolation may be used for intermediate strength levels of these materials. As used herein the strength level is the specified minimum room temperature value. The design fatigue curves of Figs. I-9.0 are defined over a cyclic range of 10 to 10^6 cycles, except that for austenitic steels, nickel-chromium alloys, and nickel-copper alloys, the design fatigue curves are extended to 10^{11} cycles in Fig. I-9.2.2. Criteria for the use of the latter curves are given in Fig. I-9.2.2 and are also presented graphically by the flow chart in Fig. I-9.2.3.

(4) *Effect of Elastic Modulus.* Multiply S_{alt} (NG-3216.1 or NG-3216.2) by the ratio of the modulus of elasticity given on the design fatigue curve to the value of the modulus of elasticity used in the analysis. Enter the applicable design fatigue curve of Figs. I-9.0 at this value on the ordinate axis and find the corresponding number of cycles on the abscissa. If the service cycle being considered is the only one which produces significant fluctuating stresses, this is the allowable number of cycles.

(5) *Cumulative Damage.* If there are two or more types of stress cycle which produce significant stresses, their cumulative effect shall be evaluated as stipulated in Steps 1 through 6 below.

Step 1: Designate the specified number of times each type of stress cycle of types 1, 2, 3, etc., will be repeated during the life of the component as $n_1, n_2, n_3, \dots, n_r$ respectively.

NOTE: In determining $n_1, n_2, n_3, \dots, n_r$ consideration shall be given to the superposition of cycles of various origins which produce a total stress difference range greater than the stress difference ranges of the individual cycles. For example, if one type of stress cycle produces 1000 cycles of a stress difference variation from zero to +60,000 psi and another type of stress cycle produces 10,000 cycles of a stress difference variation from zero to -50,000 psi, the two types of cycle to be considered are defined by the following parameters:

$$\text{Type 1 cycle: } n_1 = 1000, S_{alt1} = (60,000 + 50,000)/2 = 55,000 \text{ psi}$$

Type 2 cycle: $n_2 = 9000$, $S_{alt2} = (50,000 + 0)/2 = 25,000$ psi

Step 2: For each type of stress cycle, determine the alternating stress intensity S_{alt} by the procedures of NG-3216.1 or NG-3216.2 above. Call these quantities S_{alt1} , S_{alt2} , S_{alt3} , ..., S_{altn}

Step 3: For each value S_{alt1} , S_{alt2} , S_{alt3} , ..., S_{altn} , use the applicable design fatigue curve to determine the maximum number of repetitions which would be allowable if this type of cycle were the only one acting. Call these values N_1 , N_2 , N_3 , ..., N_n

Step 4: For each type of stress cycle, calculate the usage factors U_1 , U_2 , U_3 , ..., U_n from $U_1 = n_1/N_1$, $U_2 = n_2/N_2$, $U_3 = n_3/N_3$, ..., $U_n = n_n/N_n$

Step 5: Calculate the cumulative usage factor U from $U = U_1 + U_2 + U_3 + \dots + U_n$

Step 6: The cumulative usage factor U shall not exceed 1.0.

[98]

NG-3222.5 Thermal Stress Ratchet.

It should be noted that under certain combinations of steady state

Page 55

and cyclic loadings there is a possibility of large distortions developing as the result of ratchet action; that is, the deformation increases by a nearly equal amount for each cycle. Examples of this phenomenon are treated in this subparagraph and in NG-3227.3.

(a) The limiting value of the maximum cyclic thermal stress permitted in a portion of an axisymmetric shell loaded by steady-state internal pressure difference in order to prevent cyclic growth in diameter is as follows:

Let y'	= maximum allowable range of thermal stress computed on an elastic basis divided by the yield strength S_y^8
x	= maximum general membrane stress due to pressure difference divided by the yield strength S_y^8

(1) Case 1 - linear variation of temperature through the wall:

$$y' = \frac{1}{x} \text{ for } 0 < x < 0.5$$

$$y' = 4(1 - x) \text{ for } 0.5 < x < 1.0$$

(2) Case 2 - parabolic constantly increasing or constantly decreasing variation of temperature through the wall:

y'	= 5.2(1 - x) for 0.615 < x < 1.0 and approximately for x < 0.615 as follows:
for x	= 0.3, 0.4, 0.5
y'	= 4.65, 3.55, 2.70

(b) Use of yield strength S_y in the above relations instead of the proportional limit allows a small amount of growth during each cycle until strain hardening raises the proportional limit to S_y . If the yield strength of the material is higher than the endurance limit⁹ for the material, the latter value shall be used if there is to be a large number of cycles because strain softening may occur.

NG-3222.6 Deformation Limits.

Any deformation limits prescribed by the Design Specifications shall be satisfied.

⁸ It is permissible to use $1.5S_m$ whenever it is greater than S_y .

⁹ The endurance limit shall be taken as two times the S_a value at 10^6 cycles in the applicable fatigue curve of Figs. 1-9.0, except that for the curves of Figs. 1-9.2.1 and 1-9.2.2 the endurance limit shall be taken as two times the S_a value at 10^{11} cycles obtained from Curve A.

NG-3223 Level B Service Limits

For components operating within the temperature limits of this Section the requirements of (a) and (b) below apply.

(a) The values of Level A Service Limits (NB-3222) shall apply for Level B Service Limits. In addition, if a pressure for which Level B Limits are designated exceeds the Design Pressure Difference, the stress limits of Fig. NG-3221-1 shall apply using allowable stress intensity values of 110% of those given on Fig. NG-3221-1 and the loadings.

(b) The Design Specifications shall be satisfied.

NG-3224 Level C Service Limits

Level C Service Limits must be satisfied for Service Loadings for which they are designated by the Design Specifications and are those of one of the five methods permitted in NG-3224.1. These stress intensity limits are summarized by Fig. NG-3224-1. Dynamic instability shall be considered in meeting the load, stress, and deformation limits. The requirements of NG-3224.2 through NG-3224.6 shall also be met.

NG-3224.1 Stress Intensity Limits

(a) Elastic Analysis Method

(1) The general primary membrane stress intensity (NG-3213.6, NG-3213.8, and NG-3221.1) shall not exceed 1.5 times the allowable stress intensity S_m as given in Tables 2A and 2B, Section II, Part D, Subpart 1.

(2) The primary membrane plus primary bending stress intensity (NG-3213.7, NG-3213.8, and NG-3221.3) shall not exceed 2.25 times the allowable stress intensity S_m as given in Tables 2A and 2B, Section II, Part D, Subpart 1.

(b) Limit Load Analysis. Instead of the elastic analysis of (a) above, a limit load analysis may be performed as set forth below.

(1) The lower bound limit load L_L is determined with material yield point equal to 1.5 times the allowable stress intensity S_m at temperatures where S_m is given in Tables 2A and 2B, Section II, Part D, Subpart 1. The lower bound limit load (NG-3213.21) is that load, determined from the analysis (NG-3213.20) of an ideally plastic (nonstrain-hardening) material, which produces increasing deformations with no further increase in applied load. The lower bound load is one in which the material everywhere satisfies equilibrium and nowhere exceeds the defined material yield strength, using either the maximum shear stress theory or a strain energy of distortion theory to relate multiaxial yielding to the uniaxial case.

Page 56

Page 57

Stress Category	Primary Stresses		Secondary Stresses Membrane and Bending, Q	Peak Stresses
	Membrane, P_m (Notes (1), (2), and (3))	Bending, P_b (Notes (1), (2), and (3))		
Level C (Note (4))	P_m	$P_m + P_b$		
	1.5 S_m Elastic analysis (Note (5))	2.25 S_m Elastic analysis (Note (5))		
	L_L Limit analysis (Note (6))	L_L Limit analysis (Note (6))	Evaluation not required	Evaluation not required
	1.5 S_m Plastic analysis (Note (7))	2.25 S_m Plastic analysis (Notes (7) and (8))		
	0.6 L_u Test (Note (9))	0.6 L_u Test (Note (9))		
	S_E Stress-ratio analysis (Note (10))	$K S_E$ Stress-ratio analysis (Note (10))		

NOTES:

- (1) The symbols P_m , P_b , Q, and F do not represent single quantities, but rather sets of six quantities representing the six stress components $\sigma_1, \sigma_2, \sigma_3, \sigma_4, \sigma_5, \sigma_6$ and $\tau_1, \tau_2, \tau_3, \tau_4, \tau_5, \tau_6$.
- (2) For configurations where compressive stresses occur, the stress limits shall be revised to take into account critical buckling stresses (NG-3224.2).
- (3) When loads are transiently applied, consideration should be given to the use of dynamic load amplification and possible change in modulus of elasticity.
- (4) Where deformation is of concern in a structure, the deformation shall be limited to two-thirds the value given in Design Specifications for Level C Service Limits.
- (5) The triaxial stresses represent the algebraic sum of the three primary principal stresses ($\sigma_1 + \sigma_2 + \sigma_3$) for the combination of stress components. Where uniform tension loading is present, triaxial stresses should be limited to $6S_m$.
- (6) L_L - lower bound limit load with yield point equal to 1.5 S_m (where S_m is the value of allowable stress intensity at temperature as contained in Tables 2A and 2B, Section II, Part D, Subpart 1. The lower bound limit load is here defined as that produced from the analysis of an ideally plastic (nonstrain-hardening) material where deformations increase with no further increase in applied load. The lower bound load is one in which the material everywhere satisfies equilibrium and nowhere exceeds the defined material yield strength using either a shear theory or a strain energy of distortion theory to relate multiaxial yielding to the uniaxial case.
- (7) Elastic-plastic evaluated nominal primary stress. Strain hardening of the material may be used for the actual monotonic stress-strain curve at the temperature of loading or any approximation to the actual stress-strain curve which everywhere has a lower stress for the same strain as the actual monotonic curve may be used. Either the shear or strain energy of distortion flow rule shall be used to account for multiaxial effects.
- (8) S_u = ultimate strength at temperature. Multiaxiality effect on the ultimate strength shall be considered.
- (9) L_u is defined in NG-3224.1(a).
- (10) Stress ratio is a method of plastic analysis which uses the stress ratio combinations [combination of stresses that consider the ratio of the actual stress to the allowable plastic or elastic stress, NG-3224.1(d)] to compute the maximum load strain-hardening material can carry.

FIG. NG-3224-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITIES FOR SERVICE LEVEL C

FIG. NG-3224-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITIES FOR SERVICE LEVEL C

(2) For Service Loadings for which Level C Limits are designated, the general primary membrane stress intensity shall not exceed the lower bound limit load L_L .

(3) For Service Loadings for which Level C Limits are designated, the general primary membrane plus primary bending stress intensities shall not exceed the lower bound limit load L_L .

(c) *Plastic Analysis*. Instead of the elastic analysis of (a) above, a plastic analysis may be performed as set forth in (1) and (2) below.

(1) For Service Loadings for which Level C Limits are designated, general primary membrane stress intensity values shall not exceed 1.5 times the allowable stress intensity S_m at temperatures where S_m is given in Tables 2A and 2B, Section II, Part D, Subpart 1.

(2) For Service Loadings for which Level C Limits are designated, the general primary membrane plus primary bending stress intensities shall not exceed the greater of either one-half of the ultimate strength values at temperature or 2.25 times the allowable stress intensity values S_m at temperature as given in Tables 2A and 2B, Section II, Part D, Subpart 1.

(d) *Stress Ratio Analysis*. Instead of the elastic analysis of (a) above, a stress ratio analysis (NG-3213.23) may be performed, in which event the limits of (1) and (2) below shall be met.

(1) Service loads producing primary membrane stresses shall not result in stress intensities exceeding S_E where $S_E \leq 2.0S_m$.

(2) The stress intensity limits for other stress fields shall be as specified in A-9000. For example, for bending:

$$P_B \leq S_E \left[1 - \left(\frac{P_m}{S_E} \right)^2 \right]$$

for rectangular sections, where

$$n = 2 \quad \text{or} \quad P_B \leq \sqrt{K^2 S_E (S_E - P_m)}$$

where K is the Section Factor for $n = 1$ as determined by the method of A-9000.

(e) *Prototype or Model Tests.* For Service Loadings for which Level C Limits are designated, the limits of (a) above need not be satisfied if it can be shown from the test of a prototype or model that the specified loads (dynamic or static equivalent) do not exceed 60% of L_e , where L_e is the ultimate load or the maximum load or load combination used in the test. In using this method, account shall be taken of the size effect and dimensional tolerances which exist between the actual part and the test part or parts, as well as differences which may exist in the ultimate strength or other governing material properties of the actual part and the tested parts, to assure that the loads obtained from the test are a conservative representation of the load carrying capability of the actual structure under postulated Service Loadings for which Level C Limits are designated.

NG-3224.2 External Pressure.

The permissible equivalent static external pressure shall be taken as 150% of that permitted by the rules of NG-3133. Where dynamic pressures are involved, the permissible external pressure shall satisfy the preceding requirements or be limited to one-half the dynamic instability pressure.

NG-3224.3 Special Stress Limits.

The permissible values for special stress limits shall be taken as 150% of the values given in NG-3227 and NG-3228.1.

NG-3224.4 Secondary and Peak Stresses.

The requirements of NG-3222.2, NG-3222.4(b), NG-3222.5, and NG-3227.3 need not be satisfied.

NG-3224.5 Fatigue Requirements.

Service Loadings for which Level C Limits are designated need not be considered when applying the procedures of NG-3222.4(a) to determine whether or not a fatigue analysis is required.

NG-3224.6 Deformation Limits.

Any deformation limits prescribed by the Design Specifications shall be considered [Fig. NG-3224-1, Note (9)].

NG-3225 Level D Service Limits

If the Design Specifications specify any Service Loadings for which Level D Limits are designated [NCA-2142.4(d)], the rules contained in Appendix F may be used in evaluating these loadings, independently of all other Design and Service Loadings. In addition, when the special stress limits of NG-3227 are applicable for Level D Limits, the calculated stresses shall not exceed twice the stress limits given in NG-3227 as applied for Level A and Level B Service Limits.

NG-3227 Special Stress Limits

The following deviations from the basic stress limits are provided to cover special Service Loadings or configurations. Some of these deviations are more restrictive and some are less restrictive than the basic stress limits. Rules governing

respectively. In cases of conflict between these requirements and the basic stress limits, the rules of NG-3227 take precedence for the particular situations to which they apply. NG-3227 does not apply to threaded structural fasteners (NG-3230).

[98]

NG-3227.1 Bearing Loads

(a) The average bearing stress for resistance to crushing under the maximum load, experienced as a result of Design Loadings or of Service Loadings for which Level A Limits are designated, shall be limited to S_y at temperature, except that when the distance to a free edge is larger than the distance over which the bearing load is applied, a stress of $1.5S_y$ at temperature is permitted. For clad surfaces the yield strength of the base metal may be used if, when calculating the bearing stress, the bearing area is taken as the lesser of the actual contact area or the area of the base metal supporting the contact surface.

(b) When bearing loads are applied near free edges, such as at a protruding ledge, the possibility of a shear failure shall be considered. In the case of load stress only, the average shear stress shall be limited to $0.6S_m$. In the case of load stress plus secondary stress, the average shear stress shall not exceed (1) or (2) below:

(1) for material to which Tables 2A and 2B, Section II, Part D, Subpart 1, Note (2) applies, the lower of $0.5S_y$ at 100°F (38°C) and $0.675 S_y$ at temperature;

(2) for all other material, $0.5S_y$ at temperature.

(c) For clad surfaces, if the configuration or thickness is such that a shear failure could occur entirely within the clad material, the allowable shear stress for the cladding shall be determined from the properties of the equivalent wrought material. If the configuration is such that a shear failure could occur across a path that is partially base metal and partially clad material, the allowable shear stresses for each material shall be used when evaluating the combined resistance to this type of failure.

(d) When considering bearing stresses in pins and similar members, the S_y at temperature value is applicable, except that a value of $1.5S_y$ may be used if no credit is given to bearing area within one pin diameter from a plate edge.

[98]

NG-3227.2 Pure Shear

(a) The average primary shear stress across a section loaded in pure shear, experienced as a result of Design Loadings or Service Loadings for which Level A Limits are designated (for example, keys, shear rings), shall be limited to $0.6S_m$.

(b) The maximum primary shear, experienced as a result of Design Loadings or Service Loadings for which Level A Limits are designated exclusive of stress concentration at the periphery of a solid circular section in torsion, shall be limited to $0.8S_m$. Primary plus secondary and peak shear stresses shall be converted to stress intensities (equal to two times pure shear stress) and as such shall not exceed the basic stress limits of NG-3222.2 and NG-3222.4(b).

NG-3227.3 Progressive Distortion of Nonintegral Connections.

Screwed on caps, screwed in plugs, shear ring closures, and breechlock closures are examples of nonintegral connections which are subject to failure by bell mousing or other types of progressive deformation. If any combination of applied loads produces yielding, such joints are subject to ratcheting because the mating members may become loose at the end of each complete operating cycle and start the next cycle in a new relationship with each other, with or without manual manipulation. Additional distortion may occur in each cycle so that interlocking parts, such as threads, can eventually lose engagement. Therefore, primary plus secondary stress intensities (NG-3222.2) which result in slippage between the parts of a nonintegral connection in which disengagement could occur as a result of progressive distortion shall be limited to the value S_y (Table Y-1, Section II, Part D, Subpart 2).

NG-3227.4 Triaxial Stresses.

The algebraic sum of the three primary principal stresses ($\sigma_1 + \sigma_2 + \sigma_3$) shall not exceed four times the tabulated value of S_m .

NG-3227.5 Nozzle Piping Transition.

The P_m classification of stresses in nozzle resulting from pressure difference, external loads, and moments is applicable for that length of nozzle which lies within the limits of reinforcement given by NG-3132, whether or not nozzle reinforcement is provided. Beyond the limits of reinforcement, a P_m classification shall be applied to the general primary membrane stress intensity averaged across the section (not thickness) resulting from combined pressure difference and external mechanical loads; $P_m + P_b$ classification shall be applied to primary membrane plus primary bending stress intensities that result from Design Pressure Difference and external mechanical loads; and a $P_m + P_b + Q$ classification shall be applied to primary plus secondary stress intensities resulting from all loads including external load or moment attributable to restrained free end displacement of the attached pipe. Beyond the limits of reinforcement, the $3S_m$ limit on the range of primary plus secondary stress intensity may be exceeded as provided in NG-3228.3 except that in the evaluation of NG-3228.3(a), stresses from attached pipe thermal expansion loads and moments may also be excluded. The range of membrane plus bending stress intensity attributable solely to thermal

Page 59

expansion of the attached piping shall be $\leq 3S_m$. The nozzle, outside the reinforcement limit, shall not be thinner than the larger of the pipe thickness or the quantity $t_p (S_{mp}/S_{mn})$ where t_p is the nominal thickness of the mating pipe, S_{mp} is the allowable stress intensity value for the pipe material, and S_{mn} is the allowable stress intensity value for the nozzle material.

NG-3227.6 Applications of Elastic Analysis for Stresses Beyond the Yield Strength.

Certain of the allowable stresses permitted in the design criteria are such that the maximum stress calculated on an elastic basis may exceed the yield strength of the material. The limit on primary plus secondary stress intensity of $3S_m$ (NG-3222.2) has been placed at a level which assures shakedown to elastic action after a few repetitions of the stress cycle except in regions containing significant local structural discontinuities or local thermal stresses. These last two factors are considered only in the performance of a fatigue evaluation. Therefore:

(a) in evaluating stresses for comparison with the stress limits on other than fatigue allowables, stresses shall be calculated on an elastic basis;

(b) in evaluating stresses for comparison with fatigue allowables, all stresses except those which result from local thermal stresses [(NG-3213.12(b))] shall be evaluated on an elastic basis. In evaluating local thermal stresses, the elastic equations shall be used except that the numerical value substituted for Poisson's ratio shall be determined from the expression:

$$\nu = 0.5 - 0.2 \frac{S_y}{S_a} \text{ but not less than } 0.3$$

where

S_y

= the yield strength of the material at the mean value of the

S_a

temperature of the cycle

= the value obtained from the applicable design fatigue curve (Figs. I-9.0) for the specified number of cycles of the condition being considered

NG-3228 Applications of Plastic Analysis

The following subparagraphs provide guidance in the application of plastic analysis and some relaxation of the basic stress limits which are allowed if plastic analysis is used.

NG-3228.1 Plastic Analysis.

The limits on primary plus secondary stress intensity (NG-3222.2), thermal stress ratchet in shell (NG-3222.5), and progressive distortion of nonintegral connections (NG-3227.3) need not be satisfied at a specific location if, at the location, the procedures of (a) through (c) below are used.

(a) In evaluating stresses for comparison with the remaining stress limits, the stresses are calculated on an elastic basis.

(b) In lieu of satisfying the specific requirements of NG-3222.2, NG-3222.5, and NG-3227.3 at a specific location, the structural action is calculated on a plastic basis, and the design shall be considered to be acceptable if shakedown occurs (as opposed to continuing deformation) and if the deformations which occur prior to shakedown do not exceed specified limits. However, this shakedown requirement need not be satisfied provided the following conditions are met.

(1) The requirements on primary plus secondary stress intensity (NG-3222.2), thermal stress ratchet in shell (NG-3222.5), and progressive distortion of non-integral connections (NG-3227.3) need not be satisfied at a specific location, provided that at the location the evaluation of stresses for comparison with all the other design, service, testing, and special limits specified in NG-3220 is calculated on an elastic basis.

(2) The maximum accumulated strain at any point, as a result of cyclic operations to which plastic analysis is applied, does not exceed 5.0%.

(3) The maximum deformations do not exceed specified limits.

(4) In evaluating stresses for comparison with fatigue allowables, the numerically maximum principal total strain range shall be multiplied by one-half the modulus of elasticity of the material (Table TM, Section II, Part D, Subpart 2) at the mean value of temperature of the cycle.

(5) The material shall have a minimum specified yield strength to specified minimum ultimate strength ratio of less than 0.80.

(c) In evaluating stresses for comparison with fatigue allowables, the numerically maximum principal total strain range which occurs after shakedown shall be multiplied by one-half of the modulus of elasticity of the material (Table TM, Section II, Part D, Subpart 2) at the mean value of the temperature of the cycle.

NG-3228.2 Limit Analysis.

The limits on primary membrane stress intensity (NG-3221.1) and primary membrane plus primary bending stress intensity (NG-3221.2) need not be satisfied at a specific location if it can be shown by means of limit analysis or by tests that the specified loadings do not exceed two-thirds of the lower bound collapse load, except for those materials of Tables 2A and 2B, Section II, Part D, Subpart 1 to which Note (2) of that table is applicable. For these latter materials, the specified loading shall not exceed

Page 60

the product of the applicable permanent strain limiting factor of Table Y-2, Section II, Part D, Subpart 2 times the lower bound collapse load.

NG-3228.3 Simplified Elastic-Plastic Analysis.

The $3S_m$ limit on the range of primary plus secondary stress intensity (NG-3222.2) may be exceeded, provided that the

requirements of (a) through (f) below are met.

(a) The range of primary plus secondary membrane plus bending stress intensity, excluding thermal bending stresses, shall be $\leq 3S_m$.

(b) The value of S_a used for entering the design fatigue curve is multiplied by the factor K_e where:

$$K_e = 1.0 \text{ for } S_n \leq 3S_m$$

$$= 1.0 + \frac{(1 - n)}{n(m - 1)} \left(\frac{S_n}{3S_m} - 1 \right) \text{ for}$$

$$3S_m < S_n < 3mS_m$$

$$= 1/n \text{ for } S_n \geq 3mS_m$$

S_n

= range of primary plus secondary stress intensity

The values of the material parameters m and n for the various classes of permitted materials are as follows:

	m	n	$T_{\max}, ^\circ\text{F}$
Low alloy steel	2.0	0.2	700
Martensitic stainless steel	2.0	0.2	700
Carbon steel	3.0	0.2	700
Austenitic stainless steel	1.7	0.3	800
Nickel-chromium-iron	1.7	0.3	800
Nickel-copper	1.7	0.3	800

(c) The rest of the fatigue evaluation stays the same as required in NG-3222.4, except that the procedure of NG-3227.6 need not be used.

(d) The structure meets the thermal ratcheting requirement of NG-3222.5.

(e) The temperature does not exceed those listed in the above table for the various classes of materials.

(f) The material shall have a specified minimum yield strength to specified minimum tensile strength ratio of less than 0.80.

NG-3228.4 Tests for Level A and Level B Service Limits.

For Level A and Level B Service Limits, the limits on primary membrane plus primary bending need not be satisfied in a structure if it can be shown from the test of a prototype or model that the specified loads (dynamic or static equivalent) do not exceed 44% of L_u , where L_u is the ultimate load or the maximum load or load combination used in the test. In using this method, account shall be taken of the size effect and dimensional tolerances which may exist between the actual part and test part or parts, as well as differences which may exist in the ultimate strength or other governing material properties of the actual part and the tested parts to assure that the loads obtained from the test are a conservative representation of the load-carrying capability of the actual structure under the postulated Service Loading.

NG-3229 Design Stress Values

The design stress intensity values S_m are given in Tables 2A and 2B, Section II, Part D, Subpart 1 for core support structure material. Values for intermediate temperatures may be found by interpolation. These form the basis for the various stress limits. Values of yield strength are given in Table Y-1, Section II, Part D, Subpart 2. Values of the coefficient of thermal expansion are in Table TE, Section II, Part D, Subpart 2, and values of the modulus of elasticity are in Table TM, Section II, Part D, Subpart 2. The basis for establishing stress values is given in Appendix III. The design fatigue curves used in conjunction with NG-3222.4 are those of Figs. I-9.0.

NG-3230 STRESS LIMITS FOR THREADED STRUCTURAL FASTENERS

NG-3231 Design Conditions

(a) The rules of this paragraph apply to mechanical connections joining parts in core support structures located within a pressure retaining boundary. Devices which are used to assemble structural elements of core support structures are referred to as threaded structural fasteners. The design stress intensity values S_m and yield strength values S_y for threaded structural fasteners shall be the values given in Tables 2A and 2B, Section II, Part D, Subpart 1 and in Table Y-1, Section II, Part D, Subpart 2, respectively.

(b) The special stress limits of NG-3227 do not apply to threaded structural fasteners. For connections joining parts of pressure retaining boundaries see NB-3230.

NG-3232 Level A Service Limits

The number and cross-sectional area of threaded structural fasteners shall be such that the stress intensity limits of this paragraph are satisfied for the Service Loadings for which Level A Limits are designated in the Design Specifications. The stress intensity limits are summarized in Fig. NG-3232-1. Any deformation

Page 61

Page 62

limit prescribed in the Design Specifications shall be considered. The total axial load transferred through the fastener threads shall not go to or through zero during the specified Service Loadings.

FIG. NG-3232-1 STRESS INTENSITY LIMITS FOR DESIGN OF THREADED STRUCTURAL FASTENERS

FIG. NG-3232-1 STRESS INTENSITY LIMITS FOR DESIGN OF THREADED STRUCTURAL FASTENERS

NG-3232.1 Average Stress.

Elastic analysis of specified conditions shall show that the average primary plus secondary membrane stress including stress from preload meets the requirements of (a) through (f) below.

(a) The maximum value of the membrane stress intensity averaged across either the area of the fastener shank or the tensile stress area of the threads shall be no greater than the lesser of either $0.9S_y$ or $\frac{2}{3}S_u$, where S_y and S_u are determined at service temperature.

(b) The average shear stress across the threads when loaded in pure shear shall be no greater than $0.6S_y$, where S_y is determined at service temperature.

(c) The average value of bearing stress under the fastener head shall be no greater than $2.7S_y$, where S_y is determined at service temperature.

(d) The primary membrane stress intensity P_m due only to Design Mechanical Loads applied to the fastener shall be no greater than S_m , where S_m is determined at service temperature.

(e) If a tight joint is required, the stress due to preload shall be greater than that due to primary and secondary membrane stress excluding preload.

(f) The primary shear stress across the threads when loaded in pure shear due only to Design Mechanical Loads applied to the fastener shall be no greater than $0.6S_m$, where S_m is determined at service temperature.

NG-3232.2 Maximum Stress

(a) The maximum primary membrane and bending plus secondary membrane and bending stress intensities, produced by the combination of all primary loads and secondary loads but excluding effects of stress concentrations, shall be no greater than 1.33 times the limits of NG-3232.1(a).

(b) For torquing during installation of fasteners, the maximum value of membrane stress intensity shall be no greater than 1.2 times the limits of NG-3232.1(a) and the maximum value of membrane plus bending stress intensity shall be no greater than 1.2 times the limits of NG-3232.2(a) at installation temperature.

NG-3232.3 Fatigue Analysis of Threaded Structural Fasteners.

Unless threaded structural fasteners meet the conditions of NG-3222.4(d) and thus require no fatigue analysis, the suitability of threaded structural fasteners for cyclic service shall be determined in accordance with the procedures of (a) through (e) below.

(a) *Threaded Structural Fasteners Having Less Than 100.0 ksi (689 MPa) Tensile Strength.* Fasteners made of material which has specified minimum tensile strength of less than 100.0 ksi (689 MPa) shall be evaluated for cyclic service by the methods of NG-3222.4(e), using the applicable design fatigue curves of Figs. I-9.0 and an appropriate fatigue strength reduction factor [NG-3232.3(c)].

(b) *High Strength Threaded Structural Fasteners.* High strength fasteners may be evaluated for cyclic service by the methods of NG-3222.4(e) using the applicable design fatigue curve of Figs. I-9.0, provided:

(1) the maximum value of primary and secondary stresses, including preload, at the periphery of the fastener cross section (resulting from direct tension plus bending and neglecting stress concentrations) shall not exceed $0.9S_y$, where S_y is determined at service temperature;

(2) threads shall have a minimum thread root radius no smaller than 0.003 in. (0.076 mm);

(3) fillet radii at the end of the shank shall be such that the ratio of fillet radius to shank diameter is not less than 0.060.

(c) *Fatigue Strength Reduction Factor (NG-3213.16).* Unless it can be shown by analysis or tests that a lower value is

appropriate, the fatigue strength reduction factor used in the fatigue evaluation of threaded members shall not be less than 4.0. However, when applying the rules of (b) above for high strength fasteners, the value used shall not be less than 4.0.

(d) *Effect of Elastic Modulus.* Multiply S_{alt} (NG-3216.1 or NG-3216.2) by the ratio of the modulus of elasticity given on the design fatigue curve to the value of the modulus of elasticity used in the analysis. Enter the applicable design fatigue curve at this value on the ordinate axis and find the corresponding number of cycles on the abscissa. If the service cycle being considered is the only one which produces significant fluctuating stresses, this is the allowable number of cycles.

(e) *Cumulative Damage.* The fasteners shall be acceptable for the specified cyclic application of loads and thermal stress provided the cumulative usage factor U as determined in NG-3222.4(e)(5) does not exceed 1.0.

NG-3233 Level B Service Limits

Level A Service Limits (NG-3232) apply.

NG-3234 Level C Service Limits for Threaded Structural Fasteners

The number and cross-sectional area of threaded structural fasteners shall be such that the requirements

Page 63

of NG-3224 are satisfied for the Service Loadings for which Level C Limits are designated in the Design Specifications. For high strength structural fasteners ($S_u > 100.0$ ksi) (689 MPa), the limits of NG-3232 also apply for these Service Loadings. Any deformation limit prescribed in the Design Specifications shall be considered.

NG-3235 Level D Service Limits for Threaded Structural Fasteners

The number and cross-sectional area of threaded structural fasteners shall be such that the requirements of NG-3225 are satisfied for the Service Loadings for which Level D Limits are designated [NCA-2142.2(d)] in the Design Specifications. Any deformation limit prescribed in the Design Specifications shall be considered.

NG-3300 CORE SUPPORT STRUCTURE DESIGN

NG-3310 GENERAL REQUIREMENTS

NG-3311 Acceptability

The requirements for acceptability of a core support structure design are given in (a) through (c) below.

(a) The design shall be such that the requirements of NG-3100 and NG-3200 are satisfied.

(b) The requirements of NG-3300 are satisfied. In case of conflict between NG-3200 and NG-3300, the requirements of NG-3300 shall govern.

(c) The requirements of this Subarticle apply to internal structures, NG-1122, only as specifically stipulated by the Certificate Holder; however, the Certificate Holder shall certify that the design used for the internal structures shall not adversely affect the integrity of the core support structure.

NG-3320 DESIGN CONSIDERATIONS

NG-3321 Design and Service Loadings

The provisions of NG-3110 apply.

NG-3322 Special Considerations

The provisions of NG-3120 apply.

NG-3323 General Design Rules

The provisions of NG-3130 apply, except when they conflict with rules of this Subarticle. In case of conflict, this Subarticle governs in the design of core support structures.

NG-3350 DESIGN FOR WELDED CONSTRUCTION

NG-3351 Welded Joint Categories

(a) The term *category* as used herein defines the location of a joint. The categories established by this paragraph are for use elsewhere in this Subsection to identify special restrictions regarding type of joint permitted for the location. Figures NG-3351(a)-1 and NG-3351(a)-2 illustrate locations of some typical welded joints in each category. Joints whose design functions are neither to restrain nor support the core do not fall into any category.

(b) The *types* of joints which may be used at the various locations are defined in NG-3352.

NG-3351.1 Joints of Category A.

Joints of Category A are longitudinal joints in cylindrical members. Category A joints may be of Type I, II, or, with the following restriction, Type IV. When a Type IV joint is used in Category A, the quality factor shall be one-half that permitted for Type I or II by Table NG-3352-1 for the examination used.

NG-3351.2 Joints of Category B.

Joints of Category B are girth welds in cylindrical members. Category B joints may be of Type I, II, or, with the following restriction, Type IV or V. When Type IV or V joints are used in Category B, the quality factor shall be one-half that permitted for Type I or II by Table NG-3352-1 for the examination used.

NG-3351.3 Joints of Category C.

Joints of Category C are primarily for joining flanges to cylinders. Category C joints may be of Type I, II, III, or, with the following restriction, Type IV or V. When Type IV or V joints are used in Category C, the quality factor shall be one-half that permitted for Type I or II by Table NG-3352-1 for the examination used.

NG-3351.4 Joints of Category D.

Joints of Category D are primarily for attaching nozzles to other members. Category D joints may be of Type I, II, III, IV, V, VI, or VII.

NG-3351.5 Joints of Category E.

Joints of Category E are for joints at the ends of webs of beams. Category E joints may be of Type I, II, III, IV, V, VI, VII, or VIII.

NOTES:

- (1) See NG-3352 for definitions.
- (2) Electroslag butt welds shall be examined by radiography. Electroslag welds in ferritic material shall also be examined for their full length by the ultrasonic method after a grain refining heat treatment, when performed, or after a postweld heat treatment.
- (3) A minimum fatigue strength reduction factor of 1.0 is permitted when both sides of weld are examined; otherwise a factor of 2.0 must be used in analysis for cyclic operation.

TABLE NG-3352-1 PERMISSIBLE WELDED JOINTS AND DESIGN FACTORS

[98]

NG-3352 Permissible Types of Welded Joints

Subject to the limitations given in NG-3351, core support structures may use any of the types of joints described in the following subparagraphs, providing the quality factor n and fatigue factor f used in the analysis meet the requirements of Table NG-3352-1 for the method of examination employed. The quality factor is used by multiplying the allowable stress limit for primary and secondary categories times the quality factor in evaluating the design. The use of weld quality factor n is for static, not fatigue applications. In performing a fatigue analysis, use the fatigue factor f , designated in Table NG-3352-1, and the applicable fatigue curve in Tables I-9.0.

[98]

NG-3352.1 Type I Joints.

Full penetration welds between plates or other elements that lie approximately in the same plane or have an offset angle not greater than 30 deg. meet the intent of this subparagraph when made either as double welded butt joints, or with consumable inserts or gas backup, or with metal backing strips that are later removed, provided the backface of such joints meets the requirements of NG-4424.

NG-3352.2 Type II Joints.

Full penetration welds between plates or other elements meet the intent of this subparagraph when made either according to NG-3352.1 or with edges of the joint prepared with opposing lips to form an integral backing strip, or with metal backing strips which are not later removed, except that the suitability for cyclic operation shall be analyzed by the method of NG-3222.4 (when used, backing strips shall be continuous and any splices shall be full penetration welded).

NG-3352.3 Type III Joints.

Full penetration welds between plates or other elements that may have an offset angle up to 90 deg. meet the intent of this subparagraph when either made according to NG-3352.2 or are corner welds. Attachment of connections using deposited weld metal as reinforcement and oblique connections meet the intent of this subparagraph.

NG-3352.4 Type IV Joints.

Partial penetration welds of double groove design (minimum depth of each groove equals one-eighth times the thickness of the thinnest element) meet the intent of this subparagraph when the area of the connection is determined by the product of the throat thickness times the length of welds.

NG-3352.5 Type V Joints.

Double fillet welds meet the intent of this subparagraph when the area of the connection is determined by the product of the theoretical throat thickness times the length of the welds (Fig. NG-4427-1). Joints made having one side a single fillet and the other side a single groove meet the intent of this subparagraph.

NG-3352.6 Type VI Joints.

Partial penetration welds of single groove design meet the intent of this subparagraph when the area of the connection is determined as the product of the weld throat thickness times the length of weld.

NG-3352.7 Type VII Joints.

Single fillet welds meet the intent of this subparagraph when the area of the connection is determined as the product of the theoretical throat thickness of the fillet welds times the length of weld (Fig. NG-4427-1).

NG-3352.8 Type VIII Joints.

Intermittent fillet or plug welds meet the intent of this subparagraph when the area of the intermittent fillet weld connection is determined as the product of the theoretical throat thickness times the sum of weld lengths and the area of plug weld connection is determined as the product of the number of plug welds times the area of the minimum cross section.

NG-3352.9 Limitations on Types of Joints.

The type of joint used for service shall be one of those permitted for the Category of the joint (NG-3351). Reduced quality factors must be used for certain types of joints when used in Categories A, B, and C (Table NG-3352-1).

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NG-4000

ARTICLE NG-4000 FABRICATION AND INSTALLATION

Page 69

Page 70

NG-4100 GENERAL REQUIREMENTS

NG-4110 INTRODUCTION

(a) Core support structures (NG-1121) shall be manufactured and installed in accordance with the requirements of this Article and shall be manufactured from materials which meet the requirements of NG-2000.

(b) The rules of this Article apply to the internal structures (NG-1122) only as specifically implemented by the Certificate Holder; however, the Certificate Holder shall certify that each internal structure has been fabricated so as to avoid creating an adverse effect on the integrity of the core support structure.

NG-4120 CERTIFICATION OF MATERIAL AND FABRICATION BY CERTIFICATE HOLDER

NG-4121 Means of Certification

The Certificate Holder for an item shall certify, by application of the appropriate Code symbol and completion of the appropriate data report in accordance with NCA-8000, that the materials used comply with the requirements of NG-2000 and that the fabrication and installation comply with the requirements of this Article.

NG-4121.1 Certification of Treatments, Tests, and Examinations.

If the Certificate Holder performs treatments, tests, repairs, or examinations required by other Articles, he shall certify that he has fulfilled such requirements. Reports of all required treatments and of the results of all required tests, repairs, and examinations performed shall be available to the Inspector.

NG-4121.2 Repetition of Tensile or Impact Tests.

If during the fabrication or installation of the item the material is subjected to heat treatment that has not been covered by treatment of the test coupons (NG-2200), and that may reduce either tensile or impact properties below the required values, the tensile and impact tests shall be repeated by the Certificate Holder on test specimens taken from test coupons which have been taken and treated in accordance with the requirements of NG-2000.

NG-4122 Material Identification

Material for core support structures shall carry identification markings which will remain distinguishable until the core support structure is fabricated or installed. If the original identification markings are cut off or the material is divided, the

marks shall be accurately transferred to the parts or a coded marking shall be used to assure identification of each piece of material during subsequent fabrication or installation, unless otherwise provided by NG-2150. Material supplied with a Certificate of Compliance and welding and brazing material shall be identified and controlled so that they can be traced to the core support structure, or else a control procedure shall be employed which ensures that the specified material is used.

NG-4123 Examinations

Visual examination activities that are not referenced for examination by other specific Code paragraphs, and are performed solely to verify compliance with requirements of NG-4000, may be performed by the persons who perform or supervise the work. These visual examinations are not required to be performed by personnel and procedures qualified to NG-5500 and NG-5100, respectively, unless so specified.

NG-4125 Testing of Welding Material

All welding material shall meet the requirements of NG-2400.

Page 74

NG-4130 REPAIR OF MATERIAL

NG-4131 Elimination and Repair of Defects

Material originally accepted on delivery in which defects exceeding the limits of NG-2500 are known or discovered during the process of fabrication or installation is unacceptable. The material may be used provided the condition is corrected in accordance with the requirements of NG-2500 for the applicable product form, except:

- (a) the limitation on the depth of the weld repair does not apply;
- (b) the time of examination of the weld repairs to weld edge preparations shall be in accordance with NG-5130.

NG-4132 Documentation of Repair Welds of Base Material

The Certificate Holder who makes a repair weld, exceeding in depth the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness, shall prepare a report which shall include a chart which shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results of repair welds. In addition, all repair welds exceeding an accumulated area of 20% of the area of the part or 15 sq in. (9677 mm²), whichever is less, shall require the same documentation as welds exceeding the minimum depth.

NG-4200 FORMING, FITTING, AND ALIGNING

NG-4210 CUTTING, FORMING, AND BENDING

NG-4211 Cutting

Materials may be cut to shape and size by mechanical means such as machining, shearing, chipping, or grinding, or by thermal cutting.

NG-4211.1 Preheating Before Thermal Cutting.

When thermal cutting is performed to prepare weld joints or edges, to remove attachments or defective material, or for any other purpose, consideration shall be given to preheating the material, using preheat schedules such as suggested in Appendix D.

NG-4211.2 Material Preparation After Thermal Cutting for P-No. 8 Material.

When metal is to be removed by thermal cutting methods, additional material shall be removed by mechanical means to the extent required in the Design Specifications.

NG-4212 Forming and Bending Processes

Any process may be used to hot or cold form or bend core support structure material, including weld metal, provided the required dimensions are attained (see NG-4214 and NG-4220), and provided the specified impact properties of the material, when required, are not reduced below the minimum specified values or they are effectively restored by heat treatment following the forming operation. *Hot forming* is defined as forming with the material temperature higher than 100°F (38°C) below the lower transformation temperature of the material. When required, the process shall be qualified for impact properties as outlined in NG-4213.

NG-4213 Qualification of Forming Processes for Impact Property Requirements

A procedure qualification test shall be conducted using specimens taken from material of the same specification, grade or class, heat treatment, and with similar impact properties as required for the material in the structure. These specimens shall be subjected to the equivalent forming or bending process and heat treatment as the material in the structure. Applicable tests shall be conducted to determine that the required impact properties of NG-2300 are met after straining.

NG-4213.1 Exemptions.

Procedure qualification tests are not required for materials listed in (a) through (f) below:

(a) hot formed material, such as forgings, in which the hot forming is completed by the Material Organization prior to removal of the impact test specimens;

(b) hot formed material represented by test coupons required in either NG-2211 or NG-4121.2 which has been subjected to heat treatment representing the hot forming procedure and the heat treatments to be applied to the parts;

(c) material which does not require impact tests in accordance with NG-2300;

(d) material which has a final strain less than 0.5%;

(e) material where the final strain is less than that of a previously qualified procedure for that material;

(f) material from which the impact testing required by NG-2300 is performed on each heat and lot, as applicable, after forming.

NG-4213.2 Procedure Qualification Test.

The procedure qualification test shall be performed in the manner stipulated in (a) through (f) below.

Page 75

(a) The tests shall be performed on three different heats of material both before and after straining to establish the effects of the forming and subsequent heat treatment operations.

(b) Specimens shall be taken in accordance with the requirements of NG-2000 and shall be taken from the tension side of the strained material.

(c) The percent strain shall be established by the following formulas:

For cylinders:

$$\% \text{ strain} = 50t/R_f [1 - (R_f/R_o)]$$

For spherical or dished surfaces:

$$\% \text{ strain} = 75t/R_f [1 - (R_f/R_o)]$$

For pipe:

$$\% \text{ strain} = 100r/R$$

where

t = nominal thickness, in.

R_f	= final radius to center line of shell, in.
R_o	= original radius (equal to infinity for a flat part), in.
R	= nominal bending radius to the center line of the pipe, in.
r	= nominal radius of the pipe, in.

(d) The procedure qualification shall simulate the maximum percent surface strain, employing a bending process similar to that used in the fabrication of the material or by direct tension on the specimen.

(e) Sufficient C_v specimens shall be taken from each of the three heats of material to establish a transition curve showing both the upper and lower shelves. On each of the three heats, tests consisting of three impact specimens shall be conducted at a minimum of five different temperatures distributed throughout the transition region. The upper and lower shelves may be established by the use of one test specimen each. Depending on the product form, it may be necessary to plot the transition curves using both lateral expansion and energy level data (NG-2300). In addition, drop weight tests shall be made when required by NG-2300.

(f) Using the results of the impact test data from each of three heats, taken both before and after straining, determine either:

(1) the maximum change in NDT temperature along with:

(a) the maximum change of lateral expansion and energy at the temperature under consideration; or

(b) the maximum change in temperature at the lateral expansion or energy levels under consideration; or

(2) where lateral expansion is the acceptance criterion (NG-2300), either the maximum change in temperature or the maximum change in lateral expansion.

NG-4213.3 Acceptance Criteria for Formed Material.

To be acceptable, the formed material used in the component shall have impact properties before forming sufficient to compensate for the maximum loss of impact properties due to the qualified forming procedure used.

NG-4213.4 Requalification.

A new procedure qualification test is required when any of the following changes are made:

(a) the actual postweld heat treatment time at temperature is greater than previously qualified considering NG-2211. If the material is not postweld heat treated, the procedure must be qualified without postweld heat treatment.

(b) the maximum calculated strain of the material exceeds the previously qualified strain by more than 0.5%;

(c) preheat over 250°F (121°C) is used in the forming or bending operation but not followed by a subsequent postweld heat treatment.

NG-4214 Minimum Thickness of Fabricated Material

If any fabrication operation reduces the thickness below the minimum required to satisfy the rules of NG-3000, the material may be repaired in accordance with NG-4130.

NG-4230 FITTING AND ALIGNING

NG-4231 Fitting and Aligning Methods

Parts that are to be joined by welding may be fitted, aligned, and retained in position during the welding operation by the use of bars, jacks, clamps, tack welds, or temporary attachments.

NG-4231.1 Tack Welds.

Tack welds used to secure alignment shall either be removed completely, when they have served their purpose, or their stopping and starting ends shall be properly prepared by grinding or other suitable means so that they may be satisfactorily incorporated into the final weld. Tack welds shall be made by qualified welders using qualified welding procedures. When tack welds are to become part of

Page 76

the finished weld, they shall be visually examined in accordance with NG-5261 and defective tack welds removed.

NG-4232 Maximum Offset of Aligned Sections

Alignment of sections shall be such that the maximum offset of the finished welded joint will not be greater than $\frac{1}{2}t$, where t is the nominal thickness of the thinner section at the joint. Alternatively, smaller alignment tolerances may be specified by the Design Specifications.

NG-4232.1 Fairing of Offsets.

Any offset within the allowable limit provided shall be faired to at least a 3:1 taper, length to offset, over the width of the finished weld or, if necessary, by adding additional weld metal beyond what would otherwise be the edge of the weld. In addition, offsets greater than those stated in NG-4232 are acceptable provided the requirements of NG-3200 are met.

NG-4300 WELDING QUALIFICATIONS

NG-4310 GENERAL REQUIREMENTS

NG-4311 Types of Processes Permitted

Only those welding processes which are capable of producing welds in accordance with the welding procedure qualification requirements of Section IX and this Subsection may be used for welding core support structure material or attachments thereto. Any process used shall be such that the records required by NG-4320 can be prepared. Stud welds are not permitted.

NG-4311.2 Capacitor Discharge Welding.

Capacitor discharge welding may be used for welding temporary attachments and permanent nonstructural attachments provided that:

- (a) temporary attachments are removed in accordance with the provisions of NG-4435(b);
- (b) the energy output for permanent nonstructural attachments such as strain gages and thermocouples is limited to 125 W-sec and the minimum thickness of the material to which the attachment is made is greater than 0.09 in. (2.3 mm); and
- (c) a Welding Procedure Specification is prepared describing the capacitor discharge equipment, the combination of materials to be joined, and the technique of application; qualification of the welding procedure is not required.

NG-4311.3 Inertia and Continuous Drive Friction Welding.

Inertia and continuous drive friction welding shall not be used for the fabrication of core support structures.

NG-4320 WELDING QUALIFICATIONS, RECORDS, AND IDENTIFYING STAMPS

NG-4321 Required Qualifications

(a) Each Certificate Holder is responsible for the welding done by his organization, and he shall establish the procedure and conduct the tests required by this Article and by Section IX in order to qualify both the welding procedures and the performance of welders and welding operators who apply these procedures.

(b) Procedures, welders, and welding operators used to join permanent or temporary attachments to core support

structure parts and to make permanent or temporary tack welds used in such welding shall also meet the qualification requirements of this Article.

(c) When making procedure test plates for butt welds, consideration shall be given to the effect of angular, lateral, and end restraint on the weldment. This applies particularly to material and weld metal of 80.0 ksi (552 MPa) tensile strength or higher and heavy sections of both low and high tensile strength material. The addition of restraint during welding may result in cracking difficulties that otherwise might not occur.

NG-4322 Maintenance and Certification of Records

The Certificate Holder shall maintain a record of their qualified welding procedures and of the welders and welding operators qualified by them, showing the date and results of tests and the identification mark assigned to each welder. These records shall be reviewed, verified, and signed by any authorized individual assigned by the Certificate Holder, and they shall be accessible to the Owner and to the Inspector.

NG-4322.1 Identification of Joints by Welder or Welding Operator

(a) Each welder or welding operator shall apply the identification mark assigned to him by the Certificate Holder on or adjacent to all permanent welded joints or series of joints on which he welds. The marking shall be at intervals of 3 ft (0.9 m) or less and shall be done with either blunt nose continuous or blunt nose interrupted dot die stamps. As an alternative, the Certificate Holder shall keep a record of permanent welded joints in each item and of the welders and welding operators used in making each of the joints.

Page 77

(b) When a multiple number of permanent structural attachment welds, nonstructural welds, fillet welds, socket welds, welds of specially designed seals, weld metal cladding, hard surfacing, and tube-to-tubesheet welds are made on an item, the Certificate Holder need not identify the welder or welding operator who welded each individual joint, provided:

(1) the Certificate Holder maintains a system that will identify the welders or welding operators that made such welds on each item so that the Inspector can verify that the welders or welding operators were all properly qualified;

(2) the welds in each category are all of the same type and configuration and are welded with the same Welding Procedure Specification.

(c) The identification of welder or welding operator is not required for tack welds.

NG-4323 Welding Prior to Qualification

No welding shall be undertaken until after the welding procedures which are to be used have been qualified. Only welders and welding operators who are qualified in accordance with NG-4320 and Section IX shall be used.

NG-4324 Transferring Qualifications

The welding procedure qualifications and the performance qualification tests for welders and welding operators conducted by one Certificate Holder shall not qualify welding procedures and shall not qualify welders or welding operators to weld for any other Certificate Holder except as provided in Section IX, QW-201 and QW-300.2.

NG-4330 GENERAL REQUIREMENTS FOR WELDING PROCEDURE QUALIFICATION TESTS

NG-4331 Conformance to Section IX Requirements

All welding procedure qualification tests shall be in accordance with the requirements of Section IX as supplemented by the requirements of this Article.

NG-4333 Heat Treatment of Qualification Welds for Ferritic Material

Postweld heat treatment of procedure qualification welds shall conform to the applicable requirements of NG-4600 and Section IX

Section IX. The postweld heat treatment time at temperature shall be at least 80% of the maximum time to be applied to the weld material. The postweld heat treatment total time may be applied in one heating cycle.

NG-4334 Preparation of Test Coupons and Specimens

(a) Removal of test coupons from the test weld and the dimensions of specimens made from them shall conform to the requirements of Section IX, except that the removal of impact test coupons and the dimensions of impact test specimens shall be in accordance with (b) below.

(b) Weld deposit of each process in a multiple process weld shall, where possible, be included in the impact test specimens. When each process cannot be included in the full-size impact test specimen at the $\frac{1}{4}t$ location required by this Section, additional full-size specimens shall be obtained from locations in the test weld that will ensure that at least a portion of each process has been included in full-size test specimens. As an alternative, additional test welds can be made with each process so that full-size specimens can be tested for each process.

NG-4334.1 Coupons Representing the Weld Deposits.

Impact test specimens and testing methods shall conform to NG-2321. The impact specimen shall be located so that the longitudinal axis of the specimen is at least $\frac{1}{4}t$ and, where the thickness of the test assembly permits, not less than $\frac{3}{8}$ in. (10 mm) from the weld surface of the test assembly. In addition, when the postweld heat treatment temperature exceeds the maximum temperature specified in NG-4620 and the test assembly is cooled at an accelerated rate, the longitudinal axis of the specimen shall be a minimum of t from the edge of the test assembly. The specimen shall be transverse to the longitudinal axis of the weld with the area of the notch located in the weld. The length of the notch of the Charpy V-notch specimen shall be normal to the surface of the weld. Where drop weight specimens are required, the tension surface of the specimen shall be oriented parallel to the surface of the test assembly.

NG-4334.2 Coupons Representing the Heat Affected Zone.

Where impact tests of the heat affected zone are required by NG-4335.2, specimens shall be taken from the welding procedure qualification test assemblies in accordance with (a) through (c) below.

(a) If the qualification test material is in the form of a plate or a forging, the axis of the weld shall be

Page 78

oriented in the direction parallel to the principal direction of rolling or forging.

(b) The heat affected zone impact test specimens and testing methods shall conform to the requirements of NG-2321.2. The specimens shall be removed from a location as near as practical to a depth midway between the surface and center thickness. The coupons for heat affected zone impact specimens shall be taken transverse to the axis of the weld and etched to define the heat affected zone. The notch of the Charpy V-notch specimen shall be cut approximately normal to the material surface in such a manner as to include as much heat affected zone as possible in the resulting fracture. Where the material thickness permits, the axis of a specimen may be inclined to allow the root of the notch to align parallel to the fusion line. When a grain-refining heat treatment is not performed on welds made by the electroslag or electrogas welding process, the notch for the impact specimens shall be located in the grain-coarsened region.

(c) For the comparison of heat affected zone values with base material values [NG-4335.2(b)], Charpy V-notch specimens shall be removed from the unaffected base material at approximately the same distance from the base material surface as the heat affected zone specimens. The axis of the unaffected base material specimens shall be parallel to the axis of the heat affected zone specimens, and the axis of the notch shall be normal to the surface of the base material. When required by NG-4335.2(b)(4), drop weight specimens shall be removed from a depth as near as practical to midway between the surface and center thickness of the unaffected base material and shall be tested in accordance with the requirements of NG-2321.1.

NG-4335 Impact Test Requirements

When materials are required to be impact tested per NG-2300, impact tests of the weld metal and heat affected zone shall be performed in accordance with the following subparagraphs. The weld procedure qualification impact test specimens shall be prepared and tested in accordance with the applicable requirements of NG-2330 and NG-4334. Retests in accordance with the provisions of NG-2350 are permitted.

accordance with the provisions of NG-2350 are permitted.

NG-4335.1 Impact Tests of Weld Metal

(a) Impact tests of the weld metal shall be required for welding procedure qualification tests for production weld joints exceeding $\frac{5}{8}$ in. (16 mm) in thickness when the weld will be made on the surface or will penetrate the base material that requires impact testing in accordance with NG-2310. In addition, such testing of the weld metal is required for the welding procedure qualification tests for any weld repair to base material that requires impact testing in accordance with NG-2310, regardless of the depth of the repair.

(b) The impact test requirements and acceptance standards for welding procedure qualification weld metal shall be the same as specified in NG-2330 for the base material to be welded or repaired. Where two materials are to be joined by welding and have different fracture toughness requirements, the test requirements and acceptance standards of either material may be used for the weld metal except where otherwise specified by NCA-1280 or other parts of this Section.

NG-4335.2 Impact Tests of Heat Affected Zone

(a) Charpy V-notch tests of the heat affected zone of the welding procedure qualification test assembly are required whenever the thickness of the weld exceeds $\frac{5}{8}$ in. (16 mm) and either of the base materials requires impact testing in accordance with the rules of NG-2310. The only exceptions to the requirements are the following:

(1) the qualification for welds in P-Nos. 1 and 3 and SA-336 F12 materials that are postweld heat treated and are made by any process other than electroslog, electrogas, or thermit;

(2) the qualification for weld deposit cladding or hard-facing on any base material.

(b) Impact testing of the procedure qualification test heat affected zone, where required by this paragraph, shall be conducted in accordance with (1) through (3) below, or (4) through (6) below, and (c) below, if applicable.

(1) For tests of welding procedure qualifications for materials that require testing in accordance with NG-2331, the three Charpy V-notch heat affected zone specimens and three Charpy V-notch unaffected base material specimens shall be tested at a temperature in accordance with NG-2331(a). The Charpy V-notch impact test of the unaffected base material shall meet the requirements of Table NG-2331(a)-1. If the average lateral expansion value of the three heat affected zone specimens is equal to or greater than the average value of the unaffected base material Charpy V-notch specimens, the test shall be considered acceptable. The values and testing temperature shall be recorded on the Welding Procedure Qualification Record.

(2) If the heat affected zone Charpy V-notch average lateral expansion value of (b)(1) above is less than the unaffected base material value, and the qualification test meets the other criteria of acceptance, the Charpy V-notch test results may be recorded on the Welding Procedure Qualification Record. Data shall then be

Page 79

obtained as specified in (b)(3) below to provide an additive temperature for the adjustment of the lowest service temperature (LST) of the base material that is to be welded in production with the welding procedure that is being qualified. Alternatively, the welding procedure qualification may be rewelded and retested.

(3) The data for use in (b)(2) above shall be developed by performing additional Charpy V-notch tests on either the welding procedure qualification test heat affected zone or the unaffected base material, or both, at temperatures which provide lateral expansion values that meet or exceed those required for the thickness of the material to be welded in production [Table NG-2331(a)(1)]. The average lateral expansion data for the heat affected zone and unaffected base material shall be plotted on a lateral expansion-temperature chart. The temperature at which these two sets of data exhibit a common acceptable value of lateral expansion for the production thickness involved shall be determined. The determined temperature for the unaffected base material shall be subtracted from the similarly determined temperature for the heat affected zone. This difference, if a positive number, shall be used in (b)(2) above as the adjustment temperature. The welding procedure adjustment temperature shall be added to the highest LST established by the tests of NG-2331 for all of the base material to be welded by this procedure in production. If the temperature difference is zero or a negative number, no adjustment is required for the base material to be welded in production, and the minimum temperature established by the tests for NG-2331 will still apply as stated in (b)(1) above. Where the actual LST is not required for the production material to be welded [for example, where a testing temperature is established

by the Design Specification to determine that the material has adequate lateral expansion to meet the requirements of Table NG-2331(a)-1 at the specified test temperature], the adjustment temperature determined by the curves shall be used to establish a reduction in the specified testing temperature for the production material. The adjustment temperature shall be used to lower the specified testing temperature for any production material on which the procedure will be used.

(4) For tests of welding procedure qualification for material that requires tests in accordance with NG-2332, the T_{NDT} of the unaffected base material shall be determined to establish the test temperature for the Charpy V-notch tests. The Charpy V-notch specimens representing the heat affected zone material and the unaffected base material shall be tested at the ($T_{NDT} + 60^{\circ}\text{F}$) temperature of the unaffected base material. The Charpy V-notch impact tests of the unaffected base material shall meet the requirements of NG-2332(a). If the average lateral expansion value of the three heat affected zone specimens is equal to or greater than the average value for the unaffected base material Charpy V-notch specimens, the qualification test shall be considered acceptable, and the values and testing temperature shall be recorded on the Welding Procedure Qualification Record.

(5) If the average Charpy V-notch lateral expansion for the heat affected zone of (b)(4) above is less than that for the unaffected base material, and the qualification test meets the other criteria of acceptance, the Charpy V-notch test results may be recorded on the Welding Procedure Qualification Record. Data of (b)(6) below, which will provide an additive temperature for any base material for which the welding procedure is being qualified, shall be included. Alternatively, the welding procedure qualification may be rewelded and retested.

(6) The data for use in (b)(5) above shall be developed by performing additional Charpy V-notch tests on either the welding procedure qualification heat affected zone or the unaffected base material, or both, at temperatures which provide lateral expansion values equal to or greater than 35 mils (0.89 mm). The lateral expansion data for the heat affected zone and the unaffected base material shall be plotted on a lateral expansion-temperature chart. The temperatures at which these two sets of data exhibit a common lateral expansion value equal to or greater than 35 mils (0.89 mm) shall be determined. The determined temperature for the unaffected base material shall be subtracted from the similarly determined temperature for the heat affected zone. This difference, if a positive number, shall be used in (b)(5) above as the adjustment temperature. The adjustment temperature shall be added to the highest RT_{NDT} temperature established by the tests of NG-2332 for all of the base material to be welded by this procedure in production.

If the temperature difference is zero or a negative number, no adjustment is required for the base material to be welded in production, and the minimum temperature established by the tests for NG-2332 will still apply as stated in (b)(4) above.

Where actual RT_{NDT} is not required for the production material to be welded (for example, where a testing temperature is established by the Design Specification to determine that the RT_{NDT} is at or below the specified temperature) the additive temperature determined by the curves shall be used to establish a reduction in the specified testing temperature for the production material. The additive temperature shall be used to lower the

Page 80

specified testing temperature for any production material upon which the procedure will be used.

(c) Should the unaffected base material Charpy V-notch impact test results fail to meet the applicable requirements referenced in (b)(1) or (b)(4) above, additional unaffected base material Charpy V-notch impact tests shall be tested at higher temperatures until the applicable requirements are met. Charpy V-notch impact tests of the heat affected zone shall be tested at the same temperature at which acceptable unaffected base material properties were achieved. The rules governing the average lateral expansion of the heat affected zone relative to the average lateral expansion of the unaffected base material shall be followed as in (b)(1) through (3) or (b)(4) through (6) above, as applicable, to determine the data which are to be recorded on the Welding Procedure Qualification Record.

NG-4336 Qualification Requirements for Built-Up Weld Deposits

Built-up weld deposits for base metal reinforcement shall be qualified in accordance with the requirements of NG-4331 to NG-4335, inclusive.

NG-4400

NG-4400 RULES GOVERNING MAKING, EXAMINING, AND REPAIRING WELDS

NG-4410 PRECAUTIONS TO BE TAKEN BEFORE WELDING

NG-4411 Identification, Storage, and Handling of Welding Material

Each Certificate Holder is responsible for control of the welding electrodes and other material which is used in the fabrication and installation of core support structures (NG-4120). Suitable identification, storage, and handling of electrodes, flux, and other welding material shall be maintained. Precautions shall be taken to minimize absorption of moisture by electrodes and flux.

NG-4412 Cleanliness and Protection of Welding Surfaces

The method used to prepare the base metal shall leave the weld preparation with reasonably smooth surfaces. The surfaces for welding shall be free of scale, rust, oil, grease, and other deleterious material. The work shall be protected from deleterious contamination and from rain, snow, and wind during welding. Welding shall not be performed on wet surfaces.

NG-4420 RULES FOR MAKING WELDED JOINTS

NG-4421 Backing Rings

Backing rings shall conform to the requirements of NG-3350. The material for backing rings, when used, shall be compatible with the base metal. Permanent backing rings, when permitted by NG-3350, shall be continuous, and any splices shall be made by full penetration welds. Spacer pins shall not be incorporated into the welds.

NG-4422 Peening

Controlled peening may be performed to minimize distortion. Peening shall not be used on the initial layer, root of the weld metal, nor on the final layer unless the weld is postweld heat treated.

NG-4423 Double Welded Joints

Before applying weld metal on the second side to be welded, the root of full penetration double welded joints shall be prepared by suitable methods such as chipping, grinding, or thermal gouging, except for those processes of welding by which proper fusion and penetration are otherwise obtained and demonstrated to be satisfactory by welding procedure qualification.

NG-4424 Surfaces of Welds

As-welded surfaces are permitted. However, the surface of welds shall be sufficiently free from coarse ripples, grooves, overlaps, abrupt ridges, and valleys to meet the requirements of (a) through (e) below.

(a) The surface condition of the finished weld shall be suitable for the proper interpretation of radiographic and any other required nondestructive examinations of the welds. In those cases where there is a question regarding the surface condition on the interpretation of a radiographic film, the film shall be compared to the actual weld surface for interpretation and determination of acceptability.

(b) Reinforcements are permitted in accordance with NG-4426.

(c) Undercuts shall not exceed $\frac{1}{32}$ in. (0.8 mm) and shall not encroach on the required section thickness.

(d) Concavity on the root side of a single welded circumferential butt weld is permitted when the resulting

thickness of the weld meets the requirements of NG-3000.

(e) If the surface of the weld requires grinding to meet the above criteria, care shall be taken to avoid reducing the weld or base material below the required thickness.

NG-4425 Welding Items of Different Diameters

When items of different diameters are welded together, there shall be a gradual transition between the two surfaces. The length of the transition may include the weld. The slope of the transition shall be such that the length-offset ratio shall not be less than 3:1, unless greater slopes are shown to be acceptable by analysis in accordance with NG-3200.

NG-4426 Reinforcement of Welds

The surface of the reinforcement of all butt welded joints in core support structures may be flush with the base material or may have uniform crowns. The height of reinforcement on each face of the weld shall not exceed the following thickness:

Nominal Thickness, in.	Maximum Reinforcement, in.
Up to 1, incl.	$\frac{3}{32}$
Over 1 to 2, incl.	$\frac{1}{8}$
Over 2 to 3, incl.	$\frac{5}{32}$
Over 3 to 4, incl.	$\frac{7}{32}$
Over 4 to 5, incl.	$\frac{1}{4}$
Over 5	$\frac{5}{16}$

NG-4427 Shape and Size of Fillet Welds

Fillet welds may vary from convex to concave. The shape and size of the weld shall be in accordance with the requirements of Fig. NG-4427-1. A fillet weld in any single continuous weld may be less than the specified fillet weld dimension by not more than $\frac{1}{16}$ in. (1.6 mm), provided that the total underrun portion of the weld does not exceed 10% of the length of the weld. Individual underrun weld portions shall not exceed 2 in. (51 mm) in length. On web-to-flange welds on girders, no underrun is permitted at the ends for a length equal to twice the width of the flange. In making socket welds, a gap as shown in Fig. NG-4427-1 shall be provided prior to welding. The gap need not be present nor be verified after welding.

NG-4429 Welding of Clad Parts¹

The joint types and welding procedures used for cladding shall be such as to prevent the formation of brittle weld composition. Any such weld deposited cladding shall be examined by a liquid penetrant method in accordance with the requirements of NG-5110 and meet the acceptance standards of NG-5350. Parts welded to clad items shall be welded directly to the base metal and not to the cladding, except in the case of weld overlay cladding.

NG-4430 WELDING OF TEMPORARY ATTACHMENTS AND THEIR REMOVAL

(a) Temporary attachments (NG-1123) may be noncertified material and may be welded to the core support structure or its parts with continuous or intermittent fillet or partial penetration welds, provided the requirements of (1) through (5) below are met:

- (1) the welding procedure and the welders have been qualified in accordance with NG-4321;
- (2) the material is identified and is suitable for welding;
- (3) the material is compatible with the material to which it is attached;
- (4) the welding material is identified and compatible with the materials joined;
- (5) the welds are postweld heat treated when required by NG-4620.

(b) Removal of temporary attachments shall be accomplished as follows:

(1) the immediate area around the temporary attachment is marked in a suitable manner so that after removal the area can be identified until after it has been examined in accordance with (3) below;

(2) the temporary attachment is completely removed in accordance with the procedures of NG-4211;

(3) after the temporary attachment has been removed, the marked area is examined by the liquid penetrant or magnetic particle method in accordance with the requirements of NG-5110 and meets the acceptance standards of NG-5340 or NG-5350, whichever is applicable; this examination is not required if more than $\frac{1}{8}$ in. (3.2 mm) of material will be removed by any subsequent machining operations;

1 Welds that are exposed to corrosive action should have a resistance to corrosion that is not substantially less than that of the cladding. The use of filler metal that will deposit weld metal which is similar to the composition of the cladding material is recommended. If weld metal of different composition is used, it should have properties compatible with the application.

Page 82

Page 83

FIG. NG-4427-1 FILLET AND SOCKET WELD DETAILS AND DIMENSIONS

FIG. NG-4427-1 FILLET AND SOCKET WELD DETAILS AND DIMENSIONS

(4) as an alternative to (a)(5) above, postweld heat treatment may be deferred until after removal of the attachment.

NG-4450 REPAIR OF WELD METAL DEFECTS

NG-4451 General Requirements

Defects in weld metal detected by the examinations required by NG-5000 shall be eliminated and repaired when necessary.

NG-4452 Elimination of Surface Defects

Weld metal surface defects may be removed by grinding or machining and need not be repaired by welding, provided that the requirements of (a) through (c) below are met.

(a) The remaining thickness of the section is not reduced below that required by NG-3000.

(b) The depression, after defect elimination, is blended uniformly into the surrounding surface.

(c) The area is examined by a magnetic particle or liquid penetrant method in accordance with NG-5110 after blending and meets the acceptance standards of NG-5300 to ensure that the defect has been removed or the indication reduced to an acceptable limit. Defects detected by the visual or volumetric method and located on an interior surface need only be reexamined by the method which initially detected the defect when the interior surface is inaccessible for surface examination.

NG-4453 Requirements for Making Repairs of Welds

Excavations in weld metal, when repaired by welding, shall meet the requirements of the following subparagraphs.

NG-4453.1 Defect Removal.

Defects may be removed by mechanical means or by thermal gouging processes. The area prepared for repair shall be examined by a liquid penetrant or magnetic particle method in accordance with NG-5110 and meet the acceptance standards of NG-5340 or NG-5350. This examination is not required where defect elimination removes the full thickness of the weld and where the backside of the weld joint is not accessible for removal of examination materials.

NG-4453.2 Requirements for Welding Material, Procedures, and Welders.

The weld repair shall be made using welding material, welders, and welding procedures qualified in accordance with NG-4125 and NG-4300.

NG-4453.3 Blending of Repaired Areas.

After repair the surface shall be blended uniformly into the surrounding surface.

NG-4453.4 Examination of Repair Welds.

The examination of a weld repair shall be repeated as required for the original weld, except that it need only be reexamined by the liquid penetrant or magnetic particle method when the unacceptable indication was originally detected by the liquid penetrant or magnetic particle method and when the repair cavity does not exceed the following:

(a) $\frac{1}{3}t$ for $t \leq \frac{1}{2}$ in. (13 mm).

(b) $\frac{1}{4}$ in. (6 mm) for $\frac{1}{2}$ in. (13 mm) $< t \leq 2\frac{1}{2}$ in. (64 mm).

(c) the lesser of $\frac{3}{8}$ in. (10 mm) or 10% t for $t > 2\frac{1}{2}$ in. (64 mm).

where t equals the thickness of the weld.

NG-4500 BRAZING

Brazing is not permitted for core support structures.

NG-4600 HEAT TREATMENT

NG-4610 WELDING PREHEAT REQUIREMENTS

NG-4611 When Preheat Is Necessary

The need for and temperature of preheat are dependent on a number of factors, such as the chemical analysis, degree of restraint of the parts being joined, elevated temperature, physical properties, and material thickness. Some practices used for preheating are given in Appendix D as a general guide for the materials listed by P-Numbers of Section IX. It is cautioned that the preheating suggested in Appendix D does not necessarily ensure satisfactory completion of the welded joint and that the requirements for individual materials within the P-Number listing may be more or less restrictive. The Welding Procedure Specification for the material being welded shall specify the minimum preheating requirements under the welding procedure qualification requirements of Section IX.

NG-4612 Preheating Methods

Preheat for welding or thermal cutting, when employed, may be applied by any method which does

Page 84

not harm the base material or any weld metal already applied or which does not introduce deleterious material into the welding area which is harmful to the weld.

NG-4613 Interpass Temperature

Consideration shall be given to the limitations of interpass temperatures for quenched and tempered material to avoid detrimental effects on the mechanical properties.

NG-4620 POSTWELD HEAT TREATMENT

NG-4621 Heating and Cooling Methods

Postweld heat treatment (PWHT) may be accomplished by any suitable methods of heating and cooling, provided the required heating and cooling rates, metal temperature, metal temperature uniformity, and temperature control are maintained.

NG-4622 PWHT Time and Temperature Requirements

NG-4622.1 General Requirements.²

Except as otherwise permitted in NG-4622.7, all welds, including repair welds, shall be postweld heat treated. During postweld heat treatment, the metal temperature shall be maintained within the temperature range and for the minimum holding time specified in Table NG-4622.1-1, except as otherwise permitted in NG-4622.4(c). P-Number groups in Table NG-4622.1-1 are in accordance with Section IX, QW-420. Except as provided in NG-4624.3, PWHT shall be performed in temperature-surveyed and -calibrated furnaces, or PWHT shall be performed with thermocouples in contact with the material or attached to blocks in contact with the material. In addition, the requirements of the following subparagraphs shall apply.

NG-4622.2 Time-Temperature Recordings.

Time-temperature recordings of all postweld heat treatments shall be made available for review by the Authorized Inspector. Identification on the time-temperature recording shall be to the weld, part, or core support structure. A summary of the time-temperature recording may be provided for permanent records in accordance with NCA-4134.17.

² Any postweld heat treatment time which is anticipated to be applied to the material or item it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time

in the total at temperature specified to be applied to the test specimens.

NG-4622.3 Definition of Nominal Thickness Governing PWHT.

The nominal thickness in Table NG-4622.7(b)-1 is the thickness of the weld, the base material, or the thinner of the base materials being joined, whichever is least. It is not intended that nominal thickness include material provided for forming allowance, thinning, or mill overrun when the excess material does not exceed $\frac{1}{8}$ in. (3.2 mm) For fillet welds the nominal thickness is the throat thickness, and for partial penetration and material repair welds the nominal thickness is the depth of the weld groove or preparation.

NG-4622.4 Holding Times at Temperature

(a) The holding time at temperature as specified in Table NG-4622.1-1 shall be based on the nominal thickness of the weld. The holding time need not be continuous. It may be an accumulation of the times of multiple postweld heat treat cycles.

(b) Holding time at temperature in excess of the minimum requirements of Table NG-4622.1-1 may be used, provided that specimens so heat treated are tested in accordance with NG-2200, NG-2400, and NG-4300.

(c) Alternatively, when it is impractical to postweld heat treat at the temperature range specified in Table NG-4622.1-1, it is permissible to perform the postweld heat treatment of certain materials at lower temperatures for longer periods of time in accordance with Table NG-4622.4(c)-1 and (1), (2), and (3) below.

(1) Except for P-No. 1 materials, when welds in the materials listed in Table NG-4622.4(c)-1 are to be postweld heat treated at these lower minimum temperatures, impact test specimens for the welding procedure qualification required by NG-4300 shall be made using the same minimum temperatures and increased minimum holding time. Welding procedures, qualified at the temperature range and minimum holding time specified in Table NG-4622.1-1 and at the lower temperature and increased minimum holding time permitted by this subparagraph, are also qualified for any temperature in between. When such an in-between temperature is used, the minimum holding time shall be extrapolated from Table NG-4622.1-1 and the alternative requirements of Table NG-4622.4(c)-1.

(2) Except for P-No. 1 materials, when welds in the materials listed in Table NG-4622.4(c)-1 are to be postweld heat treated at these lower minimum temperatures, the welding material certification required by NG-2400 shall be made using the same minimum temperature and increased minimum holding time. Welding material certified at the temperature range and minimum holding time specified in Table NG-4622.1-1 and at the lower minimum temperatures and increased minimum holding time permitted by Table NG-4622.4(c)-1

1, 3, 9A Gr.1, 9B Gr.1	1050°F	2 hr/in. thickness
1, 3, 9A Gr.1, 9B Gr.1	1000°F	4 hr/in. thickness

NOTE:

(1) All other requirements of NG-4622 shall apply.

TABLE NG-4622.4(c)-1 ALTERNATIVE HOLDING TEMPERATURE AND TIMES

(3) Base material certified in accordance with NG-2200 may be postweld heat treated at the lower minimum temperatures and increased minimum holding times without recertification. Postweld heat treatment at these lower minimum temperatures and increased minimum holding times may also be the tempering operation, provided a higher tempering temperature is not required by the material specification.

NG-4622.5 PWHT Requirements When Different P-Number Materials Are Joined.

When materials of two different P-Number groups are joined by welding, the applicable postweld heat treatment shall be that specified in Table NG-4622.1-1 for the material requiring the higher PWHT temperature range.

NG-4622.7 Exemptions to Mandatory Requirements.

Postweld heat treatment in accordance with this Subarticle is not required for:

(a) nonferrous materials;

(b) welds exempted in Table NG-4622.7(b)-1;

(c) welds subjected to temperatures above the PWHT temperature range specified in Table NG-4622.1-1, provided the Welding Procedure Specification is qualified in accordance with Section IX and the base material and the deposited weld material have been heat treated at the higher temperature;

(d) postweld heat treatment is not required for core support structures constructed of P-No. 7 Type 405 material or of

Type 410 material with carbon content not exceeding 0.08%, welded with electrodes that produce an austenitic chromium-nickel weld deposit or a nonair-hardening nickel-chromium-iron weld deposit, provided the plate thickness at the welded joint does not exceed $\frac{3}{8}$ in. (10 mm).

NG-4623 PWHT Heating and Cooling Rate Requirements

Above 800°F (427°C) the rate of heating and cooling in any hourly interval shall not exceed 400°F (222°C) divided by the maximum thickness in inches of the material being heat treated, but shall not exceed 400°F (222°C) and need not be less than 100°F (56°C) in any hourly interval. During the heating and cooling period there shall not be a greater variation in temperature than 250°F (139°C) within any 15 ft (4.6 m) interval of weld length. The exceptions of (a) and (b) below are permitted.

(a) P-No. 6 material may be cooled in air from the postweld heat treatment holding temperature specified in Table NG-4622.1-1.

(b) For P-No. 7 material the cooling rate at temperatures above 1200°F (649°C) shall not exceed 100°F/hr (56°C/hr), after which the rate of cooling shall be sufficiently rapid to prevent embrittlement.

NG-4624 Methods of Postweld Heat Treatment

The postweld heat treatment shall be performed in accordance with the requirements of one of the following subparagraphs.

NG-4624.1 Furnace Heating - One Heat.

Heating the core support structure or item in a closed furnace in one heat is the preferred procedure and should be used whenever practical. The furnace atmosphere shall be controlled so as to avoid excessive oxidation, and direct impingement of flame on the core support structure or item is prohibited.

NG-4624.2 Furnace Heating - More Than One Heat.

The core support structure or item may be heated in more than one heat in a furnace, provided the furnace atmosphere control requirements of NG-4624.1 apply and overlap of the heated sections of the core support structure or item is at least 5 ft (1.5 m). When this procedure is used, the portion of the core support structure or item outside the furnace shall be shielded so that the temperature gradient is not harmful. The cross section where the core support structure or item projects from the furnace shall not intersect a structural discontinuity.

NG-4624.3 Local Heating.

Welds may be locally postweld heat treated when it is not practical to heat treat the entire core support structure or item. Local postweld heat treatment shall consist of heating a circumferential band around the core support structure or item at temperature within the ranges specified in this Subarticle. The minimum width of the controlled

Page 87

band at each side of the weld, on the face of the greatest weld width, shall be the thickness of the weld or 2 in. (51 mm), whichever is less. The temperature of the core support structure or item from the edge of the controlled band outward shall be gradually diminished so as to avoid harmful thermal gradients. This procedure may also be used for postweld heat treatment after repairs. Pages 88-88

TABLE NG-4622.7(b)-1 EXEMPTION TO MANDATORY PWHT¹

TABLE NG-4622.7(b)-1 (CONT'D)

NOTES:

- (1) The exemptions noted in this Table do not apply to electron beam welds in ferritic materials over $\frac{1}{8}$ in. in thickness.
- (2) Where the thickness of material is identified in the Type of Weld column, it is the thickness of the base material at the welded joint.
- (3) Carbon level of the pressure-retaining materials being joined.
- (4) Maximum process heat input = 150,000 J/in. The maximum resulting hardness in the procedure qualification test plate shall not exceed 35 Rc.
- (5) Intermediate postweld soak at not less than 200°F for 2 hr minimum.
- (6) Intermediate postweld soak at not less than 300°F for 2 hr minimum.

TABLE NG-4622.7(b)-1 (CONT'D)

NG-4624.4 Heating Structures Internally.

The core support structure or item may be heated internally by any appropriate means and with adequate indicating and recording temperature devices to aid in the control and maintenance of a uniform distribution of temperature in the core support structure or item. Previous to this operation, the core support structure or item should be fully enclosed with insulating material.

NG-4630 HEAT TREATMENT OF WELDS OTHER THAN THE FINAL POSTWELD HEAT TREATMENT

The holding temperature, the time at temperature, the heating rate, and the cooling rate need not conform to the requirements of this Article for heat treatments other than the final postweld heat treatment.

NG-4650 HEAT TREATMENT AFTER BENDING OR FORMING

NG-4651 Ferritic Materials

Ferritic materials may be used in the as-formed or as-bent condition, heat treated in accordance with NG-4620, fully annealed, normalized and tempered, or quenched and tempered, provided the requirements of NG-2210, NG-4212, and NG-4213 are met.

NG-4652 Austenitic and Nonferrous Materials

Heat treatment of austenitic and nonferrous materials is neither required nor prohibited after bending or forming operations.

NG-4660 HEAT TREATMENT OF ELECTROSLAG WELDS

Electroslag welds in ferritic material over $1\frac{1}{2}$ in. (38 mm) in thickness at the joints shall be given a grain refining heat treatment.

NG-4700 MECHANICAL JOINTS

NG-4710 THREADED STRUCTURAL FASTENERS

NG-4711 Thread Engagement

All threaded structural fasteners shall be engaged in accordance with the design drawings or Design Specifications.

NG-4712 Thread Lubricants

Any lubricant or compound used in threaded joints shall be suitable for the Service Conditions and shall not react unfavorably with either the service fluid or any component material in the system.

NG-4713 Removal of Thread Lubricants

All threading lubricants or compounds shall be removed from surfaces which are to be seal welded.

NG-4720 TEMPORARY FASTENERS AND THEIR REMOVAL

All fasteners used to connect temporary attachments to the core support structure shall be removed prior to operation.

American Society Of Mechanical Engineers

SEC III D1 NG-5000

ARTICLE NG-5000 EXAMINATION

Page 89

Page 90

NG-5100 GENERAL REQUIREMENTS FOR EXAMINATION

NG-5110 PROCEDURES, QUALIFICATIONS, AND EVALUATION

NG-5111 General Requirements

Nondestructive examinations shall be conducted in accordance with the examination methods of Section V, except as they may be modified by the requirements of this Article. Radiographic examination shall be by film radiography or real time radioscopes in accordance with Section V, Article 2, except that fluorescent screens are not permitted for film radiography, the geometric unsharpness shall not exceed the limits of T-285, and the penetrameters of Table NG-5111-1 shall be used in lieu of those shown in Table T-276. The requirements for the retention of radioscopic images are the same as for film radiography. Ultrasonic examination shall be in accordance with Section V, Article 5; magnetic particle examination shall be in accordance with Section V, Article 7; liquid penetrant examination shall be in accordance with Section V, Article 6; and visual examination shall be in accordance with Section V, Article 9. The examinations required by this Article or by reference to this Article shall be performed by personnel who have been qualified as required by this Article. The results of the examinations shall be evaluated in accordance with the acceptance standards of this Article.

NG-5112 Nondestructive Examination Procedures

All nondestructive examinations required by this Article shall be performed in accordance with detailed written procedures which have been proven by actual demonstration to the satisfaction of the Inspector. The procedures shall comply with the appropriate Article of Section V for the particular examination method. The digitization of radiographic film and radioscopic images shall meet the requirements of Section V, Article 2, Mandatory Appendix III, "Digital Image Acquisition, Display, and Storage for Radiography and Radioscopes." Written procedures and records of demonstration of procedure capability and personnel qualification shall be made available to the Inspector on request. At least one copy of the procedure shall be readily available to all applicable nondestructive examination personnel for reference and use.

NG-5113 Post-Examination Cleaning

Following any nondestructive examination in which examination materials are applied to the piece, the piece shall be thoroughly cleaned in accordance with applicable material or procedure specifications.

NG-5120 TIME OF EXAMINATION OF WELDS

Acceptance examinations of welds required by NG-5200 shall be performed at the time stipulated in the following subparagraphs during fabrication and installation.

(a) For welds in core support structure components, radiographic or ultrasonic examination, when required, shall be

performed after an intermediate or final postweld heat treatment if heat treatment is required by NG-4622.

(b) Magnetic particle, liquid penetrant, or visual examinations shall be performed on the final surface after any required postweld heat treatment, except that welds in P-No. 1 material may be examined either before or after postweld heat treatment. Weld surfaces that are covered with weld metal cladding shall be examined before the weld metal cladding is applied. Weld surfaces which are not accessible after a postweld heat treatment shall be examined prior to the operations which caused this inaccessibility.

NOTE:

(1) Hole (plaque) type penetrators may be used on flat plates and on objects with geometries such that the penetrator hole image is not distorted.

TABLE NG-5111-1 THICKNESS, PENETRATOR DESIGNATIONS, ESSENTIAL HOLES, AND WIRE DIAMETERS

(c) All dissimilar metal weld joints, such as in austenitic or high nickel to ferritic material or using austenitic or high nickel alloy filler metal to join ferritic material, shall be examined on the final surface after final postweld heat treatment.

NG-5130 EXAMINATION OF WELD EDGE PREPARATION SURFACES

All full penetration weld edge preparation surfaces in material 1 in. or more in thickness shall be examined by the magnetic particle or liquid penetrant method. Indications shall be evaluated in accordance with the acceptance standards of (a), (b), and (c) below.

(a) Only indications with major dimensions greater than 1/16 in. shall be considered relevant.

(b) Laminar-type discontinuities are acceptable without repair if they do not exceed 1/2 in. (13 mm) in length. The extent of all laminar-type indications exceeding 1/2 in. (13 mm) in length shall be determined by ultrasonic examination. Indications exceeding 1/2 in. (13 mm) in length shall be repaired by welding to a depth of 3/8 in. (10 mm) or the depth of the indication, whichever is less, unless the ultrasonic examination reveals that additional depth of repair is required to meet the ultrasonic

examination requirement for the product form.

(c) The following relevant indications are unacceptable:

(1) any linear indication greater than $\frac{1}{8}$ in. (3.2 mm) long for materials 1 in. (25 mm) thick to under 2 in. (51 mm) thick and $\frac{3}{16}$ in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more indications greater than $\frac{1}{16}$ in. (1.6 mm) long in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more indications greater than $\frac{1}{16}$ in. (1.6 mm) long in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

(d) Weld repairs made to weld edge preparations for Types I, II, and III welds shall be examined by the

Page 93

magnetic particle or liquid penetrant method before the surfaces become inaccessible. The examination may be performed before or after postweld heat treatment.

NG-5200 REQUIRED EXAMINATION OF WELDS

NG-5210 PERMISSIBLE EXAMINATION METHODS

Welds used in core support structures shall be examined in accordance with the requirements of this Subarticle for the type of examination specified by the Certificate Holder to meet the requirement of Table NG-3352-1. The Certificate Holder may upgrade the examination in Table NG-3352-1 to a level higher than originally specified.

NG-5220 REQUIREMENTS FOR RADIOGRAPHY OR ULTRASONIC AND LIQUID PENETRANT OR MAGNETIC PARTICLE EXAMINATION

When required by the Certificate Holder (Table NG-3352-1), welds shall be radiographically examined and the external and accessible internal weld surfaces and adjacent base metal for at least $\frac{1}{2}$ in. (13 mm) on each side of the weld examined by either the magnetic particle or liquid penetrant method. Ultrasonic examination may be substituted for radiography except for those materials and welds which have coarse grains or configurations which do not yield meaningful results by ultrasonic methods.

NG-5230 REQUIREMENTS FOR LIQUID PENETRANT OR MAGNETIC PARTICLE EXAMINATION

NG-5231 Requirements for Progressive Liquid Penetrant or Magnetic Particle Examination

When required by the Certificate Holder (Table NG-3352-1), welds shall be either liquid penetrant or magnetic particle examined progressively at the lesser of either one-third of the thickness of the weld joint or each $\frac{1}{2}$ in. (13 mm), and on the external and accessible internal weld surfaces and the adjacent base material for $\frac{1}{2}$ in. (13 mm) on each side of the weld. For welds $\frac{3}{8}$ in. (10 mm) thick or less, examination of the root, each subsequent layer, and the external and accessible internal weld surfaces and adjacent base material for at least $\frac{1}{2}$ in. (13 mm) on each side of the weld is permitted in lieu of the above.

NG-5232 Requirements for Root and Final Liquid Penetrant or Magnetic Particle Examination

When required by the Certificate Holder (Table NG-3352-1), welds shall be either liquid penetrant or magnetic particle examined after the root and final passes on the external and accessible internal weld surfaces and the adjacent base material for at least $\frac{1}{2}$ in. (13 mm) on each side of the weld.

NG-5233 Requirements for Surface Liquid Penetrant or Magnetic Particle Examination

When required by the Certificate Holder (Table NG-3352-1), welds shall be either liquid penetrant or magnetic particle

examined on the external and accessible internal weld surfaces and the adjacent base material for at least $\frac{1}{2}$ in. (13 mm) on each side of the weld.

NG-5260 REQUIREMENTS FOR SURFACE VISUAL EXAMINATION

NG-5261 Visual Examination in Addition to Other NDT Examination

All welds shall be visually examined to the acceptance criteria of NG-5361. This visual examination shall be in addition to all other required examinations.

NG-5262 Visual Examination for Weld Surface Integrity

When required by the Certificate Holder (Table NG-3352-1), welds shall be visually examined on the final surface to the acceptance criteria of NG-5362.

NG-5270 HARD SURFACING

Hard surfacing shall be examined by the liquid penetrant method in accordance with NG-2546, and the acceptance standards applicable to materials 2 in. (51 mm) thick and greater shall apply.

Page 94

NG-5300 ACCEPTANCE STANDARDS

NG-5320 RADIOGRAPHIC ACCEPTANCE STANDARDS

NG-5321 Evaluation of Indications

Indications shown on the radiographs of welds and characterized as imperfections are unacceptable under the following conditions:

- (a) any indication characterized as a crack or zone of incomplete fusion or penetration;
- (b) any other elongated indication which has a length greater than:
 - (1) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive
 - (2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. (19 mm) to $2\frac{1}{4}$ in. (57 mm), inclusive
 - (3) $\frac{3}{4}$ in. (19 mm) for t over $2\frac{1}{4}$ in. (57 mm)

where t is the thickness of the thinner portion of the weld;

(c) internal root weld conditions are acceptable when the density change as indicated in the radiograph is not abrupt; elongated indications on the radiograph at either edge of such conditions shall be unacceptable as provided in (b) above;

(d) any group of aligned indications having an aggregate length greater than t in a length of $12t$, unless the minimum distance between successive indications exceeds $6L$, in which case the aggregate length is unlimited, L being the length of the largest indication;

(e) any group of aligned indications whose aggregate length exceeds the permissible length of a single indication and with the minimum distance between these successive indications less than $3L$, L being the length of the largest indication;

(f) rounded indications in excess of that shown as acceptable in Appendix VI. Four or more rounded indications shall constitute aligned rounded indications for welds covered by Appendix VI.

NG-5330 ULTRASONIC ACCEPTANCE STANDARDS

All imperfections which produce a response equal to or greater than 50% of the reference level are unacceptable, except as noted in (a) below.

- (a)

(a) Imperfections are unacceptable if the indications exceed the reference level amplitude and have lengths exceeding:

(1) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive

(2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. (19 mm) to $2\frac{1}{4}$ in. (57 mm), inclusive

(3) $\frac{3}{4}$ in. (19 mm) for t over $2\frac{1}{4}$ in. (57 mm) where t is the thickness of the weld being examined; if a weld joins two members having different thicknesses at the weld, t is the thinner of these two thicknesses.

(b) Indications characterized as cracks, lack of fusion, or incomplete penetration are unacceptable regardless of length.

NG-5340 MAGNETIC PARTICLE ACCEPTANCE STANDARDS

NG-5341 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. After an indication has been verified to be nonrelevant, it is not necessary to reinvestigate repetitive nonrelevant indications of the same type. Nonrelevant indications which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NG-5342 Acceptance Standards

(a) Only imperfections producing indications whose major dimensions are greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

(1) any cracks and linear indications;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm), with the

Page 95

area taken in the most unfavorable location relative to the indications being evaluated.

NG-5350 LIQUID PENETRANT ACCEPTANCE STANDARDS

NG-5351 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities such as may occur from machining marks or surface conditions may produce similar indications which are nonrelevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NG-5352 Acceptance Standards

(a) Only imperfections producing indications whose major dimensions are greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

- (1) any cracks or linear indications;
- (2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);
- (3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;
- (4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) with the area taken in the most unfavorable location relative to the indications being evaluated.

NG-5360 VISUAL EXAMINATION ACCEPTANCE STANDARDS

NG-5361 General Acceptance Standards

When visual examination is performed in accordance with NG-5261, the acceptance standards of (a) and (b) below shall be met.

- (a) Weld reinforcement, underfill, undercut, and overlap shall not exceed the allowable limits of this Subsection.
- (b) The examined surface shall be free of abrupt irregularities.

NG-5362 Acceptance Standards for Visual Examination for Weld Surface Integrity

(a) When visual examination is performed in accordance with NG-5262, the weld surface shall meet the acceptance criteria given in NG-5361.

(b) The following imperfections are unacceptable:

- (1) any imperfection characterized as a crack, or lack of penetration;
- (2) rounded imperfections whose major dimension exceeds $\frac{1}{8}$ in. (3.2 mm);
- (3) four or more rounded imperfections greater than $\frac{1}{32}$ in. (0.8 mm) in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;
- (4) ten or more rounded imperfections greater than $\frac{1}{32}$ in. (0.8 mm) in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) with the area taken in the most unfavorable location relative to the imperfections being evaluated.

NG-5500 QUALIFICATIONS AND CERTIFICATION OF NONDESTRUCTIVE EXAMINATION PERSONNEL

NG-5510 GENERAL REQUIREMENTS

Organizations performing Code-required nondestructive examinations shall use personnel competent and knowledgeable to the degree specified by NG-5520. When these services are subcontracted by the Certificate Holder or Quality System Certificate Holder, he shall verify the qualification of personnel to the requirements of NG-5520. All nondestructive examinations required by this Subsection shall be performed by, and the results evaluated by, qualified nondestructive examination personnel.

NG-5520 PERSONNEL QUALIFICATION, CERTIFICATION, AND VERIFICATION

NG-5521 Qualification Procedure

(a) Personnel performing nondestructive examinations shall be qualified in accordance with the recommended guidelines of SNT-TC-1A.¹² The Employer's³ written practice required by paragraph 5 of SNT-TC-1A shall identify Employer requirements relative to the recommended guidelines. The recommended guidelines of SNT-TC-1A shall be considered minimum requirements except as modified in (1) through (5) below.

(1) Qualification of Level III nondestructive examination personnel shall be by examination.

(a) The basic and method examinations, paragraphs 8.8(1) and 8.8(2) of SNT-TC-1A, may be prepared and administered by the Employer, ASNT, or an outside agency.

(b) The specific examination, paragraph 8.8(3) of SNT-TC-1A, shall be prepared and administered by the Employer or an outside agency. The Employer or outside agency administering the specific examination shall identify the minimum grade requirement in a written program when the basic and method examinations have been administered by ASNT which issues grades on a pass/fail basis. In this case, the minimum grade for the specific examination may not be less than 80%.

(2) The written practice identified in paragraph 5 of SNT-TC-1A and the procedures used for examination of personnel shall be referenced in the Employer's Quality Program.

1 SNT-TC-1A is a recommended Practice for Nondestructive Testing Personnel Qualification and Certification published by the American Society for Nondestructive Testing, 1711 Arlingate Lane, P.O. Box 28518, Columbus, Ohio 43228-0518. SNT-TC-1A-1992 is the applicable edition

2 Personnel qualified by examination and certified to previous editions of SNT-TC-1A are considered to be qualified to the 1992 edition when the recertification is based on continuing satisfactory performance. All reexaminations and new examinations shall be in accordance with the 1992 edition.

3 Employer as used in this Article shall include: N Certificate Holders; Quality System Certificate Holders; Material Organizations who are qualified in accordance with NCA-3862(a)(1); and organizations who provide subcontracted nondestructive examination services to organizations described above.

(3) The number of hours of training and experience for nondestructive examination personnel who perform only one operation of a nondestructive examination method that consists of more than one operation, or perform a nondestructive examination of limited scope, may be less than that recommended in Table 6.3.1 of SNT-TC-1A. The training and experience times shall be described in written practice and any limitations or restrictions placed on the certification shall be described in the written practice and on the certificate.

The minimum classroom training times identified in Table 6.3.1 of SNT-TC-1A may be reduced from 8 and 16 hours to 4 and 8 hours, respectively, for visual examination personnel.

(4) For visual examination, the Jaeger Number 1 letters shall be used in lieu of the Jaeger Number 2 letters specified in paragraph 8.2(1) of SNT-TC-1A. The use of equivalent type and size letters is permitted.

(5) A Level I individual shall be qualified to perform specific setups, calibrations, and tests, and to record and evaluate data by comparison with specific acceptance criteria defined in written instructions. The Level I individual shall implement these written NDE instructions under the guidance of a Level II or III individual. A Level I individual may independently accept the results of nondestructive examinations when the specific acceptance criteria are defined in the written instructions.

(b) For nondestructive examination methods not covered by SNT-TC-1A documents, personnel shall be qualified to comparable levels of competency by subjection to comparable examinations on the particular method involved.

(c) The emphasis shall be on the individual's ability to perform the nondestructive examination in accordance with the applicable procedure for the intended application.

(d) For nondestructive examination methods that consist of more than one operation or type, it is permissible to use personnel qualified to perform one or more operations. As an example, one person may be used who is qualified to conduct radiographic examination and another may be used who is qualified to interpret and evaluate the radiographic film.

NG-5522 Certification of Personnel

(a) The Employer retains responsibility for the adequacy of the program and is responsible for certification of the Levels I, II, and III nondestructive examination personnel.

(b) When ASNT is the outside agency administering the Level III basic and method examinations [NG-5521(a)(2)], the Employer may use a letter from ASNT as evidence on which to base the certification.

(c) When an outside agency is the examining agent for Level III qualification of the Employer's personnel, the examination results shall be included with the Employer's record.

Page 97

NG-5523 Verification of Nondestructive Examination Personnel Certification

The Certificate Holder has the responsibility to verify the qualification and certification of nondestructive examination personnel employed by Material Organizations qualified by them in accordance with NCA-3820 and subcontractors who provide nondestructive examination services to them.

NG-5530 RECORDS

Personnel qualification records identified in paragraph 9.4 of SNT-TC-1A shall be retained by the Employer.

SI UNITS

Page 101

The 1995 Edition of the Boiler and Pressure Vessel Code is based on U.S. Customary (ft-lb) units of measurement which are to be regarded as the standard. This supplement is provided as a convenience to the Code user and contains SI conversion factors for units contained in the Code.

Page 102

Page 103

LIST OF SI UNITS FOR USE WITH ASME BOILER AND PRESSURE VESSEL CODE¹

Quantity	Unit	Symbol	Other Units or Limitations
Space and Time			
plane angle	radian	rad	degree (decimalized)
length	meter	m	
area	square meter	m ²	
volume	cubic meter	m ³	liter (L) for liquid only (use without prefix other than in milliliter, mL)
time	second	s	minute (min), hour (h), day (d), week, and year
Periodic and Related Phenomena			
frequency	hertz	Hz	revolutions per second (r/s)
rotational frequency	revolutions per second	s ⁻¹	revolutions per minute (r/m)
Mechanics			
mass	kilogram	kg	
density	kilogram per cubic meter	kg/m ³	
moment of inertia	kilogram · meter ²	kg · m ²	
force	newton	N	
moment of force (torque)	newton-meter	N · m	
pressure and stress	pascal	Pa	(pascal = newton per square meter)
energy, work	joule	J	kilowatt-hour (kW · h)
power	watt	W	
impact strength	joule	J	
section modulus	meter ³	m ³	
moment of section (second moment of area)	meter ⁴	m ⁴	
fracture toughness	Pa · √m		
Heat			
temperature — thermodynamic [Note (2)]	kelvin	K	degree Celsius (°C)
temperature — other than thermodynamic	degree Celsius	°C	kelvin (K)
linear expansion coefficient	meter per meter-kelvin	K ⁻¹	°C ⁻¹
quantity of heat	joule	J	
heat flow rate	watt	W	
thermal conductivity	watt per meter-kelvin	W/(m · K)	W/(m · °C)
thermal diffusivity	square meter per second	m ² /s	
specific heat capacity	joule per kilogram-kelvin	J/(kg · K)	J/(kg · °C)
Electricity and Magnetism			
electric current	ampere	A	
electric potential	volt	V	
current density	ampere per meter ²	A/m ²	
magnetic field strength	ampere per meter	A/m	

NOTES:

- (1) Conversion factors between SI units and U.S. customary are given in SI-1, "ASME Orientation and Guide for Use of SI (Metric) Units," and ASTM E 380.
- (2) Preferred use for temperature and temperature interval is degrees Celsius (°C), except for thermodynamic and cryogenic work where kelvins may be more suitable. For temperature interval, 1 K = 1°C exactly.

NOTES:

- (1) Care should be taken when converting formulas or equations that contain constant terms or factors. The value of these terms must be understood and may also require conversion.
- (2)(a) Relationships that are exact in terms of the base units are followed by a single asterisk.
- (b) The factors are written as a number greater than 1 and less than 10 with 6 or less decimal places. The number is followed by the letter E (for exponent), a plus or minus symbol, and two digits which indicate the power of 10 by which the number must be multiplied to obtain the correct value. For example: 3.523 907 E-02 is $3.523\ 907 \times 10^{-2}$ or 0.035 239 07.

**IMPORTANT INFORMATION ON THE 1998 BOILER AND PRESSURE VESSEL CODE
ADDENDA DISTRIBUTION SCHEDULE**

There is a change in the way the Addenda to the 1998 Edition of the ASME Boiler and Pressure Vessel Code are distributed. The 1998 Edition, published July 1, 1998, incorporates the 1998 Addenda revisions, additions, or deletions. There will be no separate 1998 Addenda issued in a replacement page format. Two additional Addenda to the 1998 Edition, in the form of

replacement pages, will be issued on July 1, 1999 and July 1, 2000.

The Summary of Changes published with the 1998 Edition lists and describes the revisions that are part of the 1998 Addenda. These changes are identified with a margin note, **98**, denoting the affected area.

The Addenda for 1999 and 2000 will also have a Summary of Changes and identifiers printed on the replacement pages. The revisions, additions, or deletions will be incorporated directly into the affected pages. It is advisable to retain the title sheets and all replaced pages for reference.

The effective dates for Code Editions and Addenda are described in the Foreword.

Date of Issue - July 1, 1998

(Includes all Addenda dated December 1997 and earlier)

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

The footnotes in this document are part of this American National Standard.

ADDENDA

Colored-sheet Addenda, which include additions and revisions to individual Sections of the Code, are published annually and will be sent automatically to purchasers of the applicable Sections up to the publication of the 2001 Code. The 1998 Code is available only in the loose-leaf format; accordingly, the Addenda will be issued in the loose-leaf, replacement-page format.

INTERPRETATIONS

ASME issues written replies to inquiries concerning interpretation of technical aspects of the Code. The Interpretations for each individual Section will be published separately and will be included as part of the update service to that Section. They will be issued semiannually (July and December) up to the publication of the 2001 Code. Interpretations of Section III, Divisions 1 and 2, will be included with the update service to Subsection NCA.

CODE CASES

The Boiler and Pressure Vessel Committee meets regularly to consider proposed additions and revisions to the Code and to formulate Cases to clarify the intent of existing requirements or provide, when the need is urgent, rules for materials or constructions not covered by existing Code rules. Those Cases which have been adopted will appear in the appropriate 1998 Code Cases book: (1) Boilers and Pressure Vessels and (2) Nuclear Components. Supplements will be sent automatically to the purchasers of the Code Cases books up to the publication of the 2001 Code.

FOREWORD

The American Society of Mechanical Engineers set up a committee in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. This committee is now called the Boiler and Pressure Vessel Committee.

The Committee's function is to establish rules of safety governing the design, fabrication, and inspection during construction of boilers and pressure vessels, and to interpret these rules when questions arise regarding their intent. In formulating the rules, the Committee considers the needs of users, manufacturers, and inspectors of pressure vessels. The objective of the rules is to afford reasonably certain protection of life and property and to provide a margin for deterioration in service so as to give a reasonably long, safe period of usefulness. Advancements in design and material and the evidence of experience have been recognized.

This Code contains mandatory requirements, specific prohibitions, and nonmandatory guidance for construction,¹ and inservice inspection and testing activities. The Code does not address all aspects of these activities and those aspects which are not specifically addressed should not be considered prohibited. The Code is not a handbook and cannot replace education, experience, and the use of engineering judgment. The phrase *engineering judgment* refers to technical judgments made by knowledgeable engineers experienced in the application of the Code. Engineering judgments must be consistent with Code philosophy and such judgments must never be used to overrule mandatory requirements or specific prohibitions of the Code.

¹ Construction, as used in this Foreword, in all-inclusive term comprising materials, design, fabrication, examination, inspection, testing, certification, and pressure relief.

The Committee recognizes that tools and techniques used for design and analysis change as technology progresses and expects engineers to use good judgment in the application of these tools. The designer is responsible for complying with Code rules and demonstrating compliance with Code equations when such equations are mandatory. The Code neither requires nor prohibits the use of computers for the design or analysis of components constructed to the requirements of the Code. However, designers and engineers using computer programs for design or analysis are cautioned that they are responsible for all technical assumptions inherent in the programs they use and they are responsible for the application of these programs to their design.

The Code does not fully address tolerances. When dimensions, sizes, or other parameters are not specified with tolerances, the values of these parameters are considered nominal and allowable tolerances or local variances may be considered acceptable when based on engineering judgment and standard practice as determined by the engineer.

The Boiler and Pressure Vessel Committee deals with the care and inspection of boilers and pressure vessels in service only to the extent of providing suggested rules of good practice as an aid to owners and their inspectors.

The rules established by the Committee are not to be interpreted as approving, recommending, or endorsing any proprietary or specific design or as limiting in any way the manufacturer's freedom to choose any method of design or any form of construction that conforms to the Code rules.

The Boiler and Pressure Vessel Committee meets regularly to consider revisions of the rules, new rules as dictated by technological development, Code Cases, and requests for interpretations. Only the Boiler and Pressure Vessel Committee has the authority to provide official interpretations of this Code. Requests for revisions, new rules, Code Cases, or interpretations shall be addressed to the Secretary in writing and shall give full particulars in order to receive consideration and action (see Mandatory Appendix covering preparation of technical inquiries). Proposed revisions to the Code resulting from inquiries will be presented to the Main Committee for appropriate action. The action of the Main Committee becomes effective only after confirmation by letter ballot of the Committee and approval by ASME.

to invite comments from all interested persons. After the allotted time for public review and final approval by ASME, revisions are published annually in Addenda to the Code.

Code Cases may be used in the construction of components to be stamped with the ASME Code symbol beginning with the date of their approval by ASME.

Code Editions may be used on or after the date of issue shown in the Edition. After Code revisions are approved by ASME, they may be used beginning with the date of issue shown on the Addenda. Revisions to material specifications are originated by the American Society for Testing and Materials (ASTM) and other recognized national or international organizations, and are usually adopted by ASME. However, those revisions may or may not have any effect on the suitability of material, produced to earlier editions of specifications, for use in ASME construction. ASME material specifications approved for use in each construction Code are listed in the Appendices of Section II, Parts A and B. These Appendices list, for each specification, the latest edition adopted by ASME, and earlier and later editions considered by ASME to be identical for ASME construction.

Owners of nuclear power plants are cautioned that Code Editions, Addenda, and Cases to be used in construction shall be acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

Each state and municipality in the United States and each province in Canada that adopts or accepts one or more Sections of the Boiler and Pressure Vessel Code is invited to appoint a representative to act on the Conference Committee to the Boiler and Pressure Vessel Committee. Since the members of the Conference Committee are in active contact with the administration and enforcement of the rules, the requirements for inspection in this Code correspond with those in effect in their respective jurisdictions. The required qualifications for an Authorized Inspector under these rules may be obtained from the administrative authority of any state, municipality, or province which has adopted these rules.

The Boiler and Pressure Vessel Committee in the formulation of its rules and in the establishment of maximum design and operating pressures considers materials, construction, method of fabrication, inspection, and safety devices. Permission may be granted to regulatory bodies and organizations publishing safety standards to use a complete Section of the Code by reference. If usage of a Section, such as Section IX, involves exceptions, omissions, or changes in provisions, the intent of the Code might not be attained.

Where a state or other regulatory body, in the printing of any Section of the Boiler and Pressure Vessel Code, makes additions or omissions, it is recommended that such changes be clearly indicated.

The National Board of Boiler and Pressure Vessel Inspectors is composed of chief inspectors of states and municipalities in the United States and of provinces in Canada that have adopted the Boiler and Pressure Vessel Code. This Board, since its organization in 1919, has functioned to uniformly administer and enforce the rules of the Boiler and Pressure Vessel Code. The cooperation of that organization with the Boiler and Pressure Vessel Committee has been extremely helpful.

The Code Committee does not rule on whether a component shall or shall not be constructed to the provisions of the Code. The Scope of each Section has been established to identify the components and parameters considered by the Committee in formulating the Code rules. Laws or regulations issued by municipality, state, provincial, federal, or other enforcement or regulatory bodies having jurisdiction at the location of an installation establish the mandatory applicability of the Code rules, in whole or in part, within their jurisdiction. Those laws or regulations may require the use of this Code for vessels or components not considered to be within its Scope or may establish additions or deletions in that Scope. Accordingly, inquiries regarding such laws or regulations are to be directed to the issuing enforcement or regulatory body.

Questions or issues regarding compliance of a specific component with the Code rules are to be directed to the ASME Certificate Holder (Manufacturer). Inquiries concerning the interpretation of the Code are to be directed to the ASME Boiler and Pressure Vessel Committee. ASME is to be notified should questions arise concerning improper use of an ASME Code symbol.

The specifications for materials given in Section II are identical with or similar to those of specifications published by ASTM, AWS, and other recognized national or international organizations. When reference is made in an ASME material specification to a non-ASME specification for which a companion ASME specification exists, the reference shall be

interpreted as applying to the ASME material specification. Not all materials included in the material specifications in Section II have been adopted for use in this Section. Usage is limited to those materials and grades listed in at least one of the tables of Section II, Part D, Subpart 1, identified as applicable to this Section. All materials allowed by this Section and used for construction within the scope of these rules shall be furnished in accordance with material specifications

Page ix

contained in Section II or referenced in Appendices A of Section II, Parts A and B except where otherwise provided in Code Cases or in this Section of the Code. Materials covered by these specifications are acceptable for use in items covered by the Code Sections only to the degree indicated in the applicable Section. Materials for Code use should preferably be ordered, produced, and documented on this basis. Material produced to an acceptable specification with requirements different from the requirements of the corresponding specification listed in Appendix A of Part A or Part B may also be used in accordance with the above, provided the material manufacturer or vessel manufacturer certifies with evidence acceptable to the Authorized Inspector that the corresponding ASME specification requirements of specifications listed in Appendix A of Part A or Part B have been met. Material produced to an acceptable material specification is not limited as to country of origin.

When required by context in this Section, the singular shall be interpreted as the plural, and vice-versa; and the feminine, masculine, or neuter gender shall be treated as such other gender as appropriate.

Publication of the SI (Metric) Edition of the ASME Boiler and Pressure Vessel Code was discontinued with the 1986 Edition. Effective October 1, 1986, the SI Edition was withdrawn as an ASME Boiler and Pressure Vessel Code document.

Page xi

STATEMENT OF POLICY ON THE USE OF CODE SYMBOLS AND CODE AUTHORIZATION IN ADVERTISING

ASME has established procedures to authorize qualified organizations to perform various activities in accordance with the requirements of the ASME Boiler and Pressure Vessel Code. It is the aim of the Society to provide recognition of organizations so authorized. An organization holding authorization to perform various activities in accordance with the requirements of the Code may state this capability in its advertising literature.

Organizations that are authorized to use Code Symbols for marking items or constructions which have been constructed and inspected in compliance with the ASME Boiler and Pressure Vessel Code are issued Certificates of Authorization. It is the aim of the Society to maintain the standing of the Code Symbols for the benefit of the users, the enforcement jurisdictions, and the holders of the symbols who comply with all requirements.

Based on these objectives, the following policy has been established on the usage in advertising of facsimiles of the symbols, Certificates of Authorization, and reference to Code construction. The American Society of Mechanical Engineers does not "approve," "certify," "rate," or "endorse" any item, construction, or activity and there shall be no statements or implications which might so indicate. An organization holding a Code Symbol and/or a Certificate of Authorization may state in advertising literature that items, constructions, or activities "are built (produced or performed) or activities conducted in accordance with the requirements of the ASME Boiler and Pressure Vessel Code," or "meet the requirements of the ASME Boiler and Pressure Vessel Code."

The ASME Symbol shall be used only for stamping and nameplates as specifically provided in the Code. However, facsimiles may be used for the purpose of fostering the use of such construction. Such usage may be by an association or a society, or by a holder of a Code Symbol who may also use the facsimile in advertising to show that clearly specified items will carry the symbol. General usage is permitted only when all of a manufacturer's items are constructed under the rules.

The ASME logo, which is the cloverleaf with the letters ASME within, shall not be used by any organization other than ASME.

STATEMENT OF POLICY ON THE USE OF ASME MARKING TO IDENTIFY MANUFACTURED ITEMS

The ASME Boiler and Pressure Vessel Code provides rules for the construction of boilers, pressure vessels, and nuclear components. This includes requirements for materials, design, fabrication, examination, inspection, and stamping. Items constructed in accordance with all of the applicable rules of the Code are identified with the official Code Symbol Stamp described in the governing Section of the Code.

Markings such as "ASME," "ASME Standard," or any other marking including "ASME" or the various Code Symbols shall not be used on any item which is not constructed in accordance with all of the applicable requirements of the Code.

Items shall not be described on ASME Data Report Forms nor on similar forms referring to ASME which tend to imply that all Code requirements have been met when, in fact, they have not been. Data Report Forms covering items not fully complying with ASME requirements should not refer to ASME or they should clearly identify all exceptions to the ASME requirements.

Subgroup on Materials, Construction, and Examination (SC 3C)

D. J. Haavik, *Chair*
J. F. Artuso
R. M. Attar
B. A. Erler
J. Gutierrez

SUBCOMMITTEE ON HEATING BOILERS (SC IV)

F. P. Barton, *Chair*
P. A. Molvie, *Vice Chair*
B. P. Feder, *Secretary*
R. B. Duggan
W. L. Haag, Jr.
W. M. Hiddleston
J. D. Hoh
K. M. McTague
R. I. Mullican
E. A. Nordstrom
J. L. Seigle
D. E. Tanner
S. V. Voorhees
R. H. Weigel
R. V. Wielgoszinski
J. I. Woodworth
T. L. Bedeaux, *Alternate*

Subgroup on Care and Operation of Heating Boilers (SC IV)

J. I. Woodworth, *Chair*
B. P. Feder, *Secretary*
K. J. Hoey
J. D. Hoh
F. M. Lucas
K. M. McTague
P. A. Molvie

R. I. Mullican
R. H. Weigel
T. F. Wickham
T. L. Bedeaux, Alternate

Subgroup on Cast Iron Boilers (SC IV)

K. M. McTague, *Chair*
R. B. Duggan
R. H. Weigel
T. F. Wickham
J. I. Woodworth
T. L. Bedeaux, Alternate

Subgroup on Water Heaters (SC IV)

W. L. Haag, Jr., *Chair*
T. D. Gantt
W. M. Hiddleston
F. M. Lucas
K. M. McTague
R. I. Mullican
D. Smith
D. E. Tanner
M. A. Taylor

Subgroup on Welded Boilers (SC IV)

P. A. Molvie, *Chair*
T. L. Bedeaux
D. H. Mapes
E. A. Nordstrom
J. L. Seigle
R. F. Slack, Sr.
R. P. Sullivan
D. E. Tanner
R. V. Wielgoszinski

SUBCOMMITTEE ON NONDESTRUCTIVE EXAMINATION (SC V)

T. G. McCarty, *Chair*
J. E. Batey, *Vice Chair*
F. S. Fitzgerald, *Secretary*
A. S. Birks
B. H. Clark, Jr.
W. T. Clayton
R. A. Coomes
N. Y. Faransso
H. C. Graber
O. F. Hedden
G. W. Hembree
F. B. Kovacs
J. F. Manning

Subgroup on General Requirements/Personnel Qualifications and Inquiries (SC V)

R D. McGuire, *Chair*

J. E. Batey

W. T. Clayton

N. Y. Faransso

H. C. Graber

G. W. Hembree

J. R. MacKay

J. P. Swezy

Subgroup on Surface Examination Methods (SC V)

H. C. Graber, *Chair*

S. J. Akrin

T. Alexander

A. S. Birks

B. H. Clark

R. A. Coomes

G. W. Hembree

Subgroup on Volumetric Methods (SC V)

J. E. Batey, *Chair*

S. J. Akrin

W. T. Clayton

N. Y. Faransso

H. C. Graber

G. W. Hembree

B. Kellerhall

E. K. Kietzman

F. B. Kovacs

R. W. Kruzic

J. F. Manning

W. C. McGaughey

J. R. Mitchell

Working Group on Acoustic Emissions (SG-VM) (SC V)

B. H. Clark, Jr.

P. M. Horrigan

J. F. Manning

J. R. Mitchell

Working Group on Radiography (SG-VM) (SC V)

G. W. Hembree, *Chair*

S. J. Akrin

T. Alexander

J. E. Batey

N. Y. Faransso

H. C. Graber
F. B. Kovacs

Working Group on Ultrasonics (SG-VM) (SC V)

W. T. Clayton, *Chair*
O. F. Hedden
B. Kellerhall
E. K. Kietzman
J. F. Manning
W. C. McGaughey
R. Paillaman
F. J. Sattler
M. L. Shakinovsky

SUBCOMMITTEE ON PRESSURE VESSELS (SC VIII)

T. P. Pastor, *Chair*
K. Mokhtarian, *Vice Chair*
A. J. Roby, *Secretary*
A. P. Ahrendt
V. Bogosian
S. M. Caldwell
W. J. Carter
S. C. Cyr
R. Dirscherl

ORGANIZATION OF SECTION III

1. GENERAL

Section III consists of Division 1, Division 2, and Division 3. These Divisions are broken down into Subsections and are designated by capital letters preceded by the letter "N" for Division 1, by the letter "C" for Division 2, and by the letter "W" for Division 3. The following eleven books make up the three Divisions.

Subsection NCA - General Requirements for Division 1 and Division 2

Division 1

Subsection NB - Class 1 Components

Subsection NC - Class 2 Components

Subsection ND - Class 3 Components

Subsection NE - Class MC Components

Subsection NF - Supports

Subsection NG - Core Support Structures

Subsection NH - Class 1 Components in Elevated Temperature Service

Appendices

Division 2 - Code for Concrete Reactor Vessels and Containments

Division 3 - Containment Systems and Transport Packagings for Spent Nuclear Fuel and High Level Radioactive Waste

The Division 2 book includes Subsection CC - Concrete Containments and Division 2 Appendices.

The Division 3 book includes Subsections WA and WB for General Requirements and Class TP (Type B) Containment, respectively.

2. SUBSECTIONS

Subsections are divided into Articles, Subarticles, paragraphs, and, where necessary, subparagraphs and subsubparagraphs.

3. ARTICLES

Articles are designated by the applicable letters indicated above for the Subsections followed by Arabic numbers, such as NB-1000. Where possible, Articles dealing with the same topics are given the same number in each Subsection in accordance with the following general scheme:

Article Number	Title
1000	Introduction or Scope
2000	Material
3000	Design
4000	Fabrication and Installation
5000	Examination
6000	Testing
7000	Overpressure Protection
8000	Nameplates, Stamping, and Reports

The numbering of Articles and the material contained in the Articles may not, however, be consecutive. Due to the fact that the complete outline may cover phases not applicable to a particular Subsection or Article, the rules have been prepared with some gaps in the numbering.

4. SUBARTICLES

Subarticles are numbered in units of 100, such as NB-1100.

5. SUBSUBARTICLES

Subsubarticles are numbered in units of 10, such as NB-2130, and generally have no text. When a number such as NB-1110 is followed by text, it is considered a paragraph.

6. PARAGRAPHS

Paragraphs are numbered in units of 1, such as NB-2121.

7. SUBPARAGRAPHS

Subparagraphs, when they are *major* subdivisions of a paragraph, are designated by adding a decimal followed by one or more digits to the paragraph number, such as NB-1132.1. When they are *minor* subdivisions of a paragraph, subparagraphs may be designated by lowercase letters in parentheses, such as NB-2121(a).

8. SUBSUBPARAGRAPHS

Subsubparagraphs are designated by adding lowercase letters in parentheses to the *major* subparagraph numbers, such as NB-1132.1(a). When further subdivisions of *minor* subparagraphs are necessary, subsubparagraphs are designated by adding Arabic numerals in parentheses to the subparagraph designation, such as NB-2121(a)(1).

Page xxiv

9. REFERENCES

References used within Section III generally fall into one of the following four categories.

A. References to Other Portions of Section III

When a reference is made to another Article, Subarticle, or paragraph, all numbers subsidiary to that reference shall be included. For example, reference to NB-3000 includes all material in Article NB-3000; reference to NB-3200 includes all material in Subarticle NB-3200; reference to NB-3230 includes all paragraphs NB-3231 through NB-3236.

B. References to Other Sections

Other Sections referred to in Section III are:

Section II, Materials. When a requirement for a material, or for the examination or testing of a material, is to be in accordance with a specification such as SA-105, SA-370, or SB-160, the reference is to material specifications in Section II. These references begin with the letter "S."

Section V, Nondestructive Examination. Section V references begin with the letter "T" and relate to the nondestructive examination of material or welds.

Section IX, Welding and Brazing Qualifications. Section IX references begin with the letter "Q" and relate to welding and brazing requirements.

Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components. When a reference is made to inservice inspection, the rules of Section XI shall apply.

C. Reference to Specifications and Standards Other Than Published in Code Sections

(1) Specifications for examination methods and acceptance standards to be used in connection with them are published by the American Society for Testing and Materials. At the time of publication of Section III, some such specifications were not included in Section II of this Code. A reference to ASTM E 71-64 refers to the specification so designated by and published by ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

2The American National Standards Institute (ANSI) was formerly known as the American Standards Association. Standards approved by the Association were designated by the prefix "ASA" followed by the number of the standard and the year of publication. More recently, the American National Standards Institute was known as the United States of America Standards Institute. Standards were designated by the prefix "USAS" followed by the number of the standard and the year of publication. While the letters of the prefix have changed with the name of the organization, the number of the standards have remained unchanged.

(2) Dimensional standards covering products such as valves, flanges, and fittings are sponsored and published by the American Society of Mechanical Engineers and approved by the American National Standards Institute.² When a product is to conform to such a standard, for example ANSI B16.5, the standard is approved by the American National Standards Institute. The applicable year of issue is that suffixed to its numerical designation in Table NB-3132-1, for example ANSI B16.5 - 1977. Standards published by the American Society of Mechanical Engineers are available from ASME, 22 Law Drive, Box 2300, Fairfield, NJ 07007-2300.

(3) Dimensional and other types of standards covering products such as valves, flanges, and fittings are also published by the Manufacturers Standardization Society of the Valve and Fittings Industry and are known as Standard Practices. When a product is required by these rules to conform to a Standard Practice, for example MSS SP-6, the Standard Practice referred to is published by the Manufacturers Standardization Society of the Valve and Fittings Industry, 127 Park Street, N.E., Vienna, VA 22180. The applicable year of issue of such a Standard Practice is that suffixed to its numerical designation in Table NB-3132-1, for example MSS SP-6-1963.

(4) Specifications for welding and brazing materials are published by the American Welding Society, 550 N.W. LeJeune Road, Miami, FL 33135. Specifications of this type are incorporated in Section II and are identified by the AWS designation with the prefix "SF," for example SFA-5.1.

(5) Standards applicable to the design and construction of tanks and flanges are published by the American Petroleum Institute and have designations such as API-620 and API-2000. When documents so designated are referred to in Section III, they are standards published by the American Petroleum Institute.

D. References to Appendices

Two types of Appendices are used in Section III and are designated Mandatory and Nonmandatory.

(1) Mandatory Appendices contain requirements which must be followed in construction; such references are designated by a Roman numeral followed by Arabic numerals. References to II-1100 or XI-3212, for example, relate to the Mandatory Appendices.

(2) Nonmandatory Appendices provide information or guidance for the use of Section III; such references are designated by a capital letter followed by Arabic numerals. A reference to D-1100, for example, relates to a Nonmandatory Appendix.

American Society Of Mechanical Engineers

SEC III D1 NH-1000

ARTICLE NH-1000 INTRODUCTION

Page 1

NH-1100 SCOPE

NH-1110 ASPECTS OF CONSTRUCTION COVERED BY THESE RULES

(a) Subsection NH contains rules for materials, design, fabrication, examination, testing, and overpressure relief of Class 1 components, parts, and appurtenances which are expected to function even when metal temperatures exceed those covered by the rules and stress limits of Subsection NB and Tables 2A, 2B, and 4 of Section II, Part D, Subpart 1.

(b) The rules of Subsection NH are applicable to Class 1 components independent of the type of contained fluid - water, steam, sodium, helium, or any other process fluid.

(c) The stress limits and design rules of Subsection NB are applicable only to service conditions where creep and relaxation

effects are negligible. Consequently, the rules of Subsection NB only guard against the time-independent failure modes - ductile rupture, gross distortion (buckling and incremental collapse), and fatigue. Therefore, those portions of the component, part, or appurtenance which are at all times experiencing temperatures within the range covered by Tables 2A, 2B, and 4 of Section II, Part D, Subpart 1 may be designed in compliance with the rules of NH-3000 in Subsection NH, or alternatively, in compliance with the rules of NB-3000. In addition, the rules of Subsection NH extend specific rules of NB-3000 to elevated temperature service, provided the designer can demonstrate that the combined effects of temperature, stress level, and duration of loading do not introduce significant creep effects.

(d) At temperatures and loading conditions where creep effects are significant, the design analysis shall also consider the time-dependent material properties and structural behavior by guarding against the four modes of failure shown below:

- (1) ductile rupture from short-term loadings
- (2) creep rupture from long-term loadings
- (3) creep fatigue failure
- (4) gross distortion due to incremental collapse and ratcheting

Brief guidelines are also provided in Subsection NH for the three modes of failure shown below:

- (5) loss of function due to excessive deformation
- (6) buckling due to short-term loadings
- (7) creep buckling due to long-term loadings

(e) Design procedures and materials data not contained in Subsection NH may be required to ensure the integrity or the continued functioning of the structural part during the specified service life. For example, the rules do not provide methods to evaluate deterioration which may occur in service as a result of corrosion, mass transfer phenomena, radiation effects, or other material instabilities. Nor do the rules ensure continued functional performance of deformation-sensitive structures such as valves and pumps.

NH-1120 TEMPERATURE AND SERVICE LIFE LIMITS

The rules of Subsection NH shall not be used for structural parts which will be subjected either to metal temperatures or to times greater than those values associated with the S_{mt} data for the specified material (see Appendix I-14).

NH-1130 ORGANIZATION OF SUBSECTION NH RULES

In general, the numbering of rules in Subsection NH follows the numbering system used in Subsection NB. References to Appendices are to this Subsection unless otherwise identified.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NH-2000

ARTICLE NH-2000 MATERIAL

Page 5

NH-2120 PRESSURE RETAINING MATERIALS

NH-2121 Permitted Material Specifications

(a) All materials shall comply with the rules of NB-2000, except for those paragraphs replaced by correspondingly numbered paragraphs of Subsection NH.

(b) In complying with (a) above, the base and weld material specifications of Tables I-14.1, I-14.10, and I-14.11 and the allowable stress intensities in Tables I-14.3 and I-14.13 shall be considered extensions of Tables 2A, 2B, and 4 of Section II, Part D, Subpart 1.

(c) Pressure retaining material and material welded thereto, except for temporary or nonstructural attachments as per NB-4435 and in (h) below, and except for hard surfacing metals and cladding which is 10% or less of the thickness of the base material, shall conform to the requirements of one of the specifications for material given in Tables 2A, 2B, and 4 of Section II, Part D, Subpart 1, and to all of the special requirements of this Article which apply to the product form in which the material is used.

(d) The requirements of this Article do not apply to items not associated with the pressure retaining function of a component such as shafts, stems, trim, spray nozzles, bearings, bushings, springs, wear plates, nor to seals, packing, gaskets, valve seats, and ceramic insulating material and special alloys used as seal material in electrical penetration assemblies.

(e) Material made to specifications other than those specified in Tables 2A, 2B, and 4 of Section II, Part D, Subpart 1 may be used for safety valve disks and nozzles, when the nozzles are internally contained by the external body structure, and for valve disks in line valves whose inlet connections are NPS 2¹ and less.

¹ Values of nominal pipe size have not been converted to SI.

(f) Material for instrument line fittings, NPS 1 and less, may be of material made to specifications other than those listed in Section II, Part D, provided that the fittings are in conformance with the requirements of NB-3671.4 and the material is determined to be adequate for the service conditions by the piping system designer.

(g) Welding material used in the manufacture of items shall comply with Table I-14.1(b) and the SFA specifications in Section II, Part C, and shall also comply with the applicable requirements of this Article. The requirements of this Article do not apply to material used as backing rings or backing strips in welded joints.

(h) Attachments welded to a pressure boundary (including the weld metal used to make the attachment) expecting elevated temperature service need not comply with the limits on upper values of service temperatures and times, as stated in Tables 2A, 2B, and 4 of Section II, Part D, Subpart 1, provided the rules listed below are met.

(1) The design of the welded attachment complies with the rules in NH-3354.

(2) The attachment material and weld are of similar alloy composition to the pressure boundary material.²

NH-2123 Design Stress Intensity Values

Design stress intensity values for material are listed in Tables 2A, 2B, and 4 of Section II, Part D, Subpart 1, as extended in coverage by the rules of NH-2121(b). With the exception of attachment material covered by NH-2121(h), no material shall be used at metal and design temperatures above those for which values are given.

² Different product forms, such as castings, are acceptable for the attachment.

NH-2160 DETERIORATION OF MATERIAL IN SERVICE

(a) Consideration of deterioration of material caused by service is generally outside the scope of this Subsection.

Page 8

It is the responsibility of the Owner to select material suitable for the conditions stated in the Design Specifications (NCA-3250), with specific attention being given to the effects of service conditions upon the properties of the material.

(b) Special consideration shall be given to the influence of elements such as copper and phosphorus on the effects of irradiation on the properties of material (including welding material) in the core belt line region of the reactor vessel. Any special requirement shall be specified in the Design Specifications (NCA-3252 and NB-3124). When so specified, the check analysis shall be made in accordance with the base metal specification and in accordance with NB-2420 for the welding material.

(c) The combination of fabrication induced cold working and subsequent elevated temperature service may affect

time-dependent material properties.

NH-2433 Delta Ferrite Determination

A determination of delta ferrite shall be performed on A-No. 8 weld material (QW-442, Section IX) backing filler metal (consumable inserts); bare electrode, rod, or wire filler metal; or weld metal, except that delta ferrite determinations are not required for SFA-5.4, Type 16-8-2, nor A-No. 8 weld filler metal to be used for weld metal cladding.

NH-2433.1 Method.

Delta ferrite determinations of welding material, including consumable insert material, shall be made using a magnetic measuring instrument and weld deposits made in accordance with (b) below. Alternatively, the delta ferrite determinations for welding materials may be performed by the use of chemical analysis of NB-2432 in conjunction with Fig. NB-2433.1-1.

- (a) Calibration of magnetic instruments shall conform to AWS-A4.2-91.
- (b) The weld deposit for magnetic delta ferrite determination shall be made in accordance with NB-2432.1(c).
- (c) A minimum of six ferrite readings shall be taken on the surface of the weld deposit. The readings obtained shall be averaged to a single Ferrite Number.

NH-2433.2 Acceptance Standards.

For design temperatures up to and including 800°F (427°C), the minimum acceptable delta ferrite shall be 5-FN (Ferrite Number). For design temperatures exceeding 800°F (427°C), the delta ferrite shall be limited to the range FN-3 to FN-10. The results of the delta ferrite determination shall be included in the Certified Material Test Report of NB-2130 or NB-4120.

NH-2539 Repair of Plates by Welding

The Material Organization may repair by welding material from which defects have been removed, provided the depth of the repair cavity does not exceed one-third of the nominal thickness and the requirements of the following subparagraphs are met. The weld material used to make weld repairs shall meet the requirements of Table I-14.1(b) and NB-2400. Additional requirements may be listed in the Design Specifications, as per NB-2160, to assure that the repair weld is adequate for the service conditions. Prior approval of the Certificate Holder shall be obtained for the repair of plates to be used in the manufacture of vessels.

(NB-2539.1 through NB-2539.7 are unchanged.)

NH-2540 FATIGUE ACCEPTANCE TEST

- (a) For 304 and 316 austenitic stainless steel components intended for service where conditions for levels A, B, and C do not satisfy the limits of T-1324(a) and (b), a uniaxial fatigue acceptance test of each lot of material shall be performed.
- (b) The fatigue test shall be performed in air at 1,100°F (593°C) at an axial strain range of 1.0% with a one-hour hold period at the maximum positive strain point in each cycle. Test-specimen location and orientation shall be in accordance with the general guidance of SA-370, paras. 6.1.1 and 6.1.2 and the applicable product specifications. Testing shall be conducted in accordance with ASTM Standard E 606. The test shall exceed 200 cycles without fracture or a 20% drop in the load range.
- (c) Failure to meet this requirement shall be cause for rejection of the lot for use in Class 1 elevated temperature components.
- (d) The definition of "lot" shall be obtained from the material specification. Where more than one definition is provided by the specification, the definition used to establish the tensile properties shall govern. Either the Material Organization or N-Type Certificate Holder may perform the lot qualification test.
- (e) Retesting is permitted. Two additional specimens shall be tested and both specimens must pass the cyclic life requirement. Further retests are not permitted.

NH-3100 GENERAL REQUIREMENTS FOR DESIGN

NH-3110 SCOPE, ACCEPTABILITY, AND LOADINGS

NH-3111 Scope

(a) Article NH-3000 is a self-contained set of design rules for metal structures serving as component pressure retaining boundaries under temperatures which may at times exceed those for which design stress-intensity values S_m are given in Section II, Part D, Subpart 1.

(b) The design rules of NB-3000 shall apply only where specifically called out by the rules of Subsection NH.

NH-3111.1 Acceptability.

An acceptable design of a Class 1 Component for elevated temperature service is one which:

(a) is capable of meeting the functional requirements as specified in the Design Specifications (NCA-3250); and

(b) satisfies the requirements for a design by analysis, either in NH-3200 or in the Design Rules for components, while under the loadings described in NH-3111.2 and the Design Specifications; and

(c) satisfies the general design rules of NH-3130 and the applicable design rules for components which apply to a vessel (NH-3300), pump (NH-3400), valve (NH-3500), or piping (NH-3600). The Design Specifications shall state which Subarticle applies to the given component.

(d) As an alternative to (b) and (c) above, the rules of NB-3000 may be applied to those portions of the component which never experience temperatures above those for which design stress-intensity values are given in Tables 2A, 2B, and 4 of Section II, Part D, Subpart 1.

NH-3111.2 Loadings.

The loadings that shall be taken into account in designing a component include but are not limited to the following:

(a) internal and external pressure;

(b) weight of the component and its normal contents under service or test loadings, including additional pressure due to static and dynamic head of liquids;

(c) superimposed loads such as from other components, operating equipment, insulation, corrosion-resistant or erosion-resistant linings and piping;

(d) wind loads, snow loads, vibrations, and earthquake loads where specified;

(e) reactions of supporting lugs, rings, saddles, or other types of supports;

(f) temperature effects;

(g) impact forces caused by either external or internal events.

NH-3112 Design Parameters

(a) The design parameters are the pressures, temperatures, and mechanical load forces applicable to the design of nuclear power plant components. The simplest set of design parameters would consist of the temperature, pressure, and load forces that exist at some given time.

(b) To design a zone of a component for service at elevated temperature, two types of design parameter data are needed in the Design Specifications (NCA-3250): first, an expected loading history which consists of how each design parameter varies as a function of time; and second, a list of events which occur under each loading category defined in NH-3113.

(c) The design parameter data stipulated in (1) and (2) below shall be specified in the Design Specifications (NCA-3250) for each component:

(1) the loading event history to be used in the structural analysis;

(2) the design parameters from which the designer will determine the most severe loading for each loading category defined in NH-3113. (If fluid conditions are specified, the designer eventually must convert the data to metal temperatures and surface pressures.)

(d) It is permissible for the designer to establish the zone boundaries inside the component. However, the

Page 16

zone boundaries and applicable design parameters shall be fully described in the Stress Report.

NH-3112.1 Specified Pressure

(a) The specified internal and external pressure histories shall describe pressure values not less than the maximum pressure differences between the inside and outside of the pressure boundary in a given zone of the component, or between any two chambers of a combination unit.

(b) The specified pressure histories shall be used in the computations made to show compliance with the limits of NH-3200.

(c) All pressures referred to in this Article are to be taken as the value above atmospheric pressure unless otherwise stated.

NH-3112.2 Specified Temperature.

The specified temperature history for the loading category shall enable the designer to describe a temperature value not less than the maximum local wall averaged temperature that will exist in the structural metal in a given zone of the component. And for the particular analyses of Service Loadings (NH-3113.2), the designer shall determine the history of the maximum local metal temperature in a given zone and shall use these metal temperature histories in the computations to show compliance with the limits of NH-3200.

(a) All temperatures referred to in this Article are the metal temperatures expressed in degrees Fahrenheit (F) unless otherwise stated.

(b) Where a component is heated by trace heating, induction coils, jacketing, or by internal heat generation, the designer shall consider the effect of such heating in the establishment of the design temperature histories.

(c) Elevated temperature mechanical properties are extremely sensitive to temperature. The Design Specifications shall specify any inaccuracies in temperature measurement and prediction that are to be considered in the design analyses made to show compliance with the limits of NH-3200.

NH-3112.3 Specified Mechanical Load Forces.

The specified load forces for a given loading category (NH-3113) shall define all expected mechanical loadings which must be considered in design analysis computations made to show compliance with the limits of NH-3200.

NH-3113 Loading Categories

Loading categories used in this Subsection consist of Design Loading, Service Loadings (Levels A, B, C, and D), and

Test Loadings.

NH-3113.1 Design Loadings.

The specified design parameters for the Design Loadings category shall equal or exceed those of the most severe combination of coincident pressure, temperature, and load forces specified under events which cause Service Level A Loadings (NH-3113.3) for the same zone of the component. These specified design parameters for Design Loadings shall be called Design Temperature, Design Pressure, and Design Mechanical Loads. These specified design parameters shall be used in computations to show compliance with the requirements on Design Limits in NH-3222.1.

NH-3113.2 Service Loadings.

Each loading to which the component may be subjected shall be categorized in accordance with the following definitions and shall be described in the Design Specifications (NCA-3250) in such detail as will provide a complete basis for construction in accordance with these rules. The Service Loading categories shall be as defined in the next four subparagraphs below.

NH-3113.3 Level A Service Loadings.

Level A Service Loadings are any loadings arising from system startup, operation in the design power range, hot standby, and system shut-down, and excepting only those loadings covered by Levels B, C, and D Service Loadings or Test Loading.

NH-3113.4 Level B Service Loadings.

(From incidents of moderate frequency.) These are deviations from Level A Service Loadings that are anticipated to occur often enough that design should include a capability to withstand the loadings without operational impairment. The events which cause Level B Service Loadings include those transients which result from any single operator error or control malfunction, transients caused by a fault in a system component requiring its isolation from the system, and transients due to loss of load or power. These events include any abnormal incidents not resulting in a forced outage and also forced outages for which the corrective action does not include any repair of mechanical damage. The estimated duration of a Level B Service Loading shall be included in the Design Specifications.

NH-3113.5 Level C Service Loadings.

(From infrequent incidents.) These are deviations from Level A Service Loadings which require shutdown for correction of the loadings or repair of damage in the system. The conditions have a low probability of occurrence, but are included to provide assurance that no gross loss of structural integrity will result as a concomitant effect of any damage developed in the system. The total number of postulated occurrences for such events may

Page 17

not exceed 25. If more than 25 are expected, then some types of events must be evaluated by the more stringent requirements of the Level B Service Limits.

NH-3113.6 Level D Service Loadings.

(From limiting faults.) These are combinations of loadings associated with extremely low probability, postulated events whose consequences are such that the integrity and operability of the nuclear energy system may be impaired to the extent that only considerations of public health and safety are involved.

NH-3113.7 Test Loadings.

These are pressure loadings which occur during hydrostatic tests, pneumatic tests, and leak tests. Other types of tests shall be classified under either Service Level A or B loading categories given in the above subparagraphs. If any elevated temperature tests are specified as Test Loadings for a component, then these loadings shall be considered as part of the Service Level B loadings for the component.

NH-3114 Load Histogram

NH-3114.1 Level A and B Service Events.

The Design Specifications (NCA-3250) shall include an expected loading history or load histogram for all Service Loadings from Level A and B service events (including all Test Loadings). These load histograms shall give all expected mechanical load forces, pressure, and temperatures for the various zones of the component throughout its service life. These histograms are then used in meeting the analysis requirements of NH-3200.

NH-3114.2 Level C Service Events.

The Design Specifications shall include a time history of the design parameters during each type of Level C Service event. However, these events need not be specified as to time of occurrence during the service life of the component. The design parameter data shall be used in meeting the analysis requirements of NH-3200. Level C Service events may be assumed as occurring between operational cycles (NH-3213.15) of Level A Service events unless otherwise specified in the Design Specifications (NCA-3250).

NH-3130 GENERAL DESIGN RULES

NH-3131 Scope

Design rules generally applicable to all components are provided in NH-3130. The Design Subarticle for the specific component provides rules applicable to that particular component. In case of conflict between NH-3130 and the design rules for a particular component, the component design rules shall govern.

NH-3132 Dimensional Standards for Standard Products

Dimensions of standard products shall comply with the standards and specifications listed in Table NB-3132-1 when the standard or specification is referenced in the specific design Subarticle. However, compliance with these standards does not replace or eliminate the requirements for stress analysis when called for by the design Subarticle for a specific component.

NH-3133 Size Restrictions in Nozzle, Branch, Piping, and Other Connections

The size of certain design features is restricted on nozzle, branch, piping, and other connections. Table NH-3133-1 provides assistance in understanding where the limits are imposed.

NH-3134 Leak Tightness

Where a system leak tightness greater than that required or demonstrated by a hydrostatic test is required, the leak tightness requirements for each component shall be set forth in the applicable Design Specifications (NCA-3250).

NH-3135 Attachments

Lugs, brackets, stiffeners, and other attachments may be welded, bolted, or studded to the outside or inside of a component. The effects of attachments in producing thermal stresses, stress concentrations, and restraints on pressure retaining members shall be taken into account in the analysis for compliance with design criteria of NH-3200. For example, the temperature patterns around an attachment may lead to higher thermal stresses simply due to the *cooling-fin effect* of the attachment.

NH-3136 Reinforcement for Openings

See NH-3330 and NH-3643 for the rules applicable to reinforcement of openings in the pressure boundaries of vessels and piping, respectively. For all other components, the rules of NH-3330 shall apply unless otherwise specified in the Design Specifications.

**TABLE NH-3133-1
SIZE RESTRICTIONS ON CONNECTIONS**

Reference Paragraph	Service Conditions	Item Description	Item	Nominal Sizes Allowed
NB-3352.4(d) & NB-3337.3	Non-creep	Partial penetration nozzle welds & other Cat. D welds	Vessel	All
NH-3352(e) & NH-3337.3	Creep	(as above)	Vessel	OD ≤ 1-in.
NB-3431, NH-3337.3 & NB-3352.4(d)	Non-creep	Partial penetration piping connection weld	Pump	OD ≤ 2-in.

TABLE NH-3133-1 SIZE RESTRICTION ON CONNECTIONS

NH-3137 Design Considerations Related to Other Articles of the Code

NH-3137.1 Design Considerations for Static Pressure Testing.

Since every component and appurtenance must eventually undergo a static pressure test, the designer shall ensure that such a test can be performed. If the only available test fluid can leave harmful residues on surfaces, the design shall preferably be such as to leave surfaces accessible for cleaning following the static pressure test. Special access hatches as well as drain lines may be required.

NH-3137.2 Design Considerations for Overpressure Protection of the System

(a) Each component and the system into which it will be installed shall be protected against overpressure events as required by the rules on overpressure protection of Class 1 components and systems exposed to elevated temperature service.

service.

(b) The Service Loadings listed in the Design Specifications include those overpressure events which the designer shall consider in the design of that particular component. However, the component designer shall also review the final design to determine if additional

Page 19

overpressure transients can arise from one of the following:

- (1) failure of nonpressure boundary parts of the component;
- (2) failure of external power sources to the component;
- (3) functioning of the component in conjunction with specified plant and system service conditions (Levels A, B, C, and D).

The designer shall report to the Owner regarding all sources of overpressure transients that can arise from (1), (2), and (3) above.

NH-3138 Elastic Follow-up

(a) When only a small portion of the structure undergoes inelastic strains while the major portion of the structural system behaves in an elastic manner, the calculations of load forces, stresses, and strains shall consider the behavior of the entire structural system. In these cases, certain areas may be subjected to strain concentrations, due to the elastic follow-up of the rest of the connected structure. These abnormally large strain concentrations may result when structural parts of different flexibility are in series and the flexible portions are highly stressed. Examples include:

- (1) local reduction in size of a cross section or local use of a weaker material;
 - (2) in a piping system of uniform size, a configuration for which most of the system lies near the hypothetical straight line connecting the two anchors, (stiffeners, flanges, or other stiff members), and with only a small portion departing from this line. Then the small portion absorbs most of the expansion strain.
- (b) If possible, the above conditions should be avoided in design. Where such conditions cannot be avoided, the analysis required in NH-3250 will determine the acceptability of the design to guard against harmful consequences of elastic follow-up.

NH-3139 Welding

NH-3139.1 Abrupt Changes in Mechanical Properties at Weld and Compression Contact Junctions.

In satisfying the requirements of NH-3000, particular considerations shall be given to the design, analysis, and construction of welded and compression contact junctions between two materials which have different mechanical properties. Such properties at elevated temperatures include thermal expansion, creep rate, creep ductility, and fatigue life. Examples of such junctions are bimetallic welds, brazed joints, compression or shrink fits, bolted flanges, and other types of mechanical joints. When temperatures cycle between low temperatures and elevated temperatures, the inelastic strains can result in significant localized strain accumulation near an abrupt change in mechanical properties.

NH-3139.2 Weld Design.

All welds shall comply with the rules of NB-3350. Exceptions to this requirement are allowed only if a specific callout is made in either NH-3400, NH-3500, or NH-3600.

NH-3200 DESIGN BY ANALYSIS

NH-3210 DESIGN CRITERIA

NH-3211 Requirements for Acceptability

For a Class 1 component intended for elevated temperature service, the requirements for the acceptability of a design based on analysis shall be as stipulated in (a) through (d) below.

(a) The design shall be such that the calculated or experimentally determined stresses, strains, and deformations will not exceed the limits described in this Subarticle;

(b) The design details shall conform to the rules of NH-3100 and to those given in subsequent Subarticles applicable to the specific component;

(c) If the designer has demonstrated that the elevated temperature service parameters (time, stress level, and temperature) do not introduce significant creep effects¹, then the experimental and analytical methods of Subsection NB shall be applicable. The other restrictions on temperature maxima that appear in Subsection NB [see NB-3228.5(e)] shall not apply provided the designer demonstrates the validity of values and methods for the higher temperatures.

(d) For portions of the component which do not experience elevated temperature service, the rules of NB-3000 may be used to satisfy (a) and (b) above. Alternatively, properties and allowable stress values from Subsection NB may be used in analyses to demonstrate compliance with the rules of NH-3200.

NH-3212 Basis for Determining Stress, Strain, and Deformation Quantities

1 A report documenting the experimental data or calculations based on experimental data or both shall demonstrate that the elevated temperature service does not introduce creep effects. This document shall be incorporated into the Stress Report (NCA-3550) and shall be approved by the Owner by means of a certified revision to the Design Specifications (NCA-3250).

(a) For elastic analysis allowed by Subsection NH, the maximum shear stress theory shall be used to

Page 20

determine stress intensities for multiaxial stress states (NB-3212).

(b) For inelastic analysis required by Subsection NH, appropriate multiaxial stress-strain relationships and associated flow rules shall be used to combine multiaxial stresses and strains.

NH-3213 Terms Relating to Analysis

In Subsection NH, the stress and strain limits for design evaluation are related to the type of structural behavior under loading. The controlled quantities fall into two general categories:²

(a) *Load Controlled Quantities* - These quantities are stress intensities which are computed on the basis of equilibrium with the applied forces and moments during plant operation. Included in this category are general primary membrane, local primary membrane, primary bending stresses, and secondary stresses with a large amount of elastic follow-up.

(b) *Deformation Controlled Quantities* - These quantities are strains, cyclic strain ranges, or deformations which result from load deflection and/or strain compatibility.

Other terms used in Subsection NH relating to structural analysis are defined in the subparagraphs of NH-3213.

NH-3213.1 Elastic Stress Intensity.

Elastic stress intensity³ is the equivalent intensity of combined stress. In short, the stress intensity is defined as twice the maximum shear stress. In other words, the stress intensity is the difference between the algebraically largest principal stress and the algebraically smallest principal stress at a given point. Tensile stresses are considered positive and compressive stresses are considered negative.

2 Note that the expansion stress (P) defined in NB-3222.3 is deleted for Subsection NH. Stresses resulting from the constraint of free end displacement and the effects of anchor motion shall be assigned to either primary or secondary stress categories [see NH-3213(a), NH-3213(b), and NH-3217].

3 This definition of stress intensity is not related to the definition of stress intensity applied in the field of Fracture Mechanics.

NH-3213.2 Gross Structural Discontinuity.

Gross structural discontinuity is a geometric or material discontinuity which affects the stress or strain distribution through the entire wall thickness of the pressure retaining member. Gross discontinuity type stresses are those portions

of the actual stress distributions that produce net bending and membrane force resultants when integrated through the wall thickness. Examples of gross structural discontinuities are head-to-shell and flange-to-shell junctions, nozzles, and junctions between shells of different diameters or thicknesses.

NH-3213.3 Local Structural Discontinuity.

Local structural discontinuity is a geometric or material discontinuity which affects the stress or strain distribution through a fractional part of the wall thickness. The stress distribution associated with a local discontinuity causes only very localized types of deformation or strain and has no significant effect on the shell type discontinuity deformation. Examples are small fillet radii, small attachments, and partial penetration welds.

NH-3213.4 Normal Stress.

Normal stress is the component of stress normal to the plane of reference. This is also referred to as direct stress. Usually the distribution of normal stress is not uniform through the thickness of a part, so this stress is considered to be made up in turn of two components, one of which is uniformly distributed and equal to the average value of stress across the thickness under consideration, and the other of which varies from this average value with the location across the thickness.

NH-3213.5 Shear Stress.

Shear stress is the component of stress tangent to the plane of reference.

NH-3213.6 Membrane Stress.

Membrane stress is the component of normal stress which is uniformly distributed and equal to the average of stress across the thickness of the section under consideration.

NH-3213.7 Bending Stress.

Bending stress is the variable component of normal stress described in NH-3213.4. The variation may or may not be linear across the thickness.

NH-3213.8 Primary Stress.

Primary stress is any normal stress or a shear stress developed by an imposed loading which is necessary to satisfy the laws of equilibrium of external and internal forces and moments. The basic characteristic of a primary stress is that it is not self-limiting. Primary membrane stress is divided into general and local categories. A general primary membrane stress is one which is so distributed in the structure that no redistribution of load occurs as a result of yielding. Examples of primary stresses are:

- (a) general membrane stress in a circular cylindrical or a spherical shell due to internal pressure or to distributed live loads;
- (b) bending stress in the central portion of a flat head due to pressure;
- (c) stresses in piping due to net cross section load forces (normal or shear) arising from thermal expansion of structural material.

NH-3213.9 Secondary Stress.

Secondary stress is a normal stress or a shear stress developed by the constraint of adjacent material or by self-constraint of the structure, and thus it is normally associated with a deformation controlled quantity at elevated temperatures. The basic characteristic of a secondary stress is that it is self-limiting. Local yielding and minor distortions can satisfy the conditions which cause the stress to occur and failure from one application of the stress is not to be expected. Examples of secondary stresses are:

- (a) bending stress at a gross structural discontinuity;

(b) bending stress in piping where loads cannot cause excessive creep deformation (e.g., buckling or dimpling) in a local region;

(c) bending stress due to a linear radial thermal strain (αT) profile through the thickness of a section;

(d) bending stress due to an equivalent linear thermal strain profile for the actual (nonlinear) strain profile [The equivalence is based on having the linear profile exert the same net bending moment as that from the actual profile (NH-3213.13).];

(e) stress produced by an axial temperature distribution in a cylindrical shell;

(f) stress produced by the temperature difference between a nozzle and the shell to which it is attached.

NH-3213.10 Local Primary Membrane Stress.

Cases arise in which a membrane stress produced by pressure or other mechanical loading and associated with a primary or a discontinuity effect produces excessive distortion in the transfer of load to other portions of the structure. Conservatism requires that such a stress be classified as a local primary membrane stress even though it has some characteristics of a secondary stress. A stressed region may be considered local if the distance over which the membrane stress intensity exceeds $1.1S_o$ does not extend in the meridional direction more than $1.0 \sqrt{Rt}$, where R is the minimum midsurface radius of curvature and t is the minimum thickness in the region considered. Regions of local primary stress intensity involving axisymmetric membrane stress distributions which exceed $1.1S_o$ shall not be closer in the meridional direction than $2.5 \sqrt{Rt}$, where R is defined as $(R_1 + R_2)/2$ and t is defined as $(t_1 + t_2)/2$ (where t_1 and t_2 are the minimum thicknesses at each of the regions considered, and R_1 and R_2 are the minimum midsurface radii of curvature at these regions where the membrane stress intensity exceeds $1.1S_o$). Discrete regions of local primary membrane stress intensity, such as those resulting from concentrated loads acting on brackets, where the membrane stress intensity exceeds $1.1S_o$, shall be spaced so that there is no overlapping of the areas in which the membrane stress intensity exceeds $1.1S_o$. An example of a local primary membrane stress is the membrane stress in a shell produced by external load and moment at a permanent support or at a nozzle connection.

NH-3213.11 Peak Stress.

Peak stress is that increment of stress which is additive to the primary plus secondary stresses by reason of local discontinuities or local thermal stress [see NH-3213.13(b)] including the effects (if any) of stress concentrations. The basic characteristic of a peak stress is that it does not cause any noticeable distortion and is objectionable only as a possible source of a fatigue crack or a brittle fracture, and, at elevated temperatures, as a possible source of localized rupture or creep-fatigue failure. A stress which is not highly localized falls into this category if it is of a type which cannot cause noticeable distortion. Examples of peak stresses are:

(a) the thermal stress in the austenitic steel cladding of a carbon steel component;

(b) certain thermal stresses which may cause fatigue but not distortion;

(c) the stress at a local structural discontinuity;

(d) surface stresses produced by thermal shock.

NH-3213.13 Thermal Stress.

Thermal stress is a self-balancing stress produced by a nonuniform distribution of temperature or by differing thermal coefficients of expansion. Thermal stress is developed in a solid body whenever a volume of material is prevented from assuming the size and shape that it normally should under a change in temperature. For the purpose of establishing allowable stresses, two types of thermal stress are recognized, depending on the volume or area in which distortion takes place, as described in the following subsubparagraphs.

(a) General thermal stress is associated with distortion of the structure in which it occurs. When thermal stresses are to be considered as primary or secondary loadings, they are in this category. For example, see T-1331(d).

(b)

no significant distortion. Such stresses shall be considered only from the fatigue standpoint and are therefore classified as peak stresses. Examples of local thermal stresses are:

(1) the stress in a small hot spot in a vessel wall;

(2) the difference between the actual stress and the equivalent linear stress resulting from a radial temperature distribution in a cylindrical shell;

(3) the thermal stress in a cladding material which has a coefficient of expansion different from that of the base metal.

Page 22

NH-3213.15 Operational Cycle.

Operational cycle is defined as the initiation and establishment of new parameter values followed by a return to the values which prevailed at the beginning of the cycle. The description of the types of plant and system operating conditions which may occur in a nuclear energy system, are beyond the scope of Section III.

NH-3213.16 Strain Cycle.

Strain cycle is a condition in which the strain goes from an initial value, through an algebraic maximum value and an algebraic minimum value and then returns to the initial value. In cases where creep or ratcheting are present in the cycle, there will not be a return to the initial strain value. Instead the designer will have to examine the hysteresis loop for inelastic analysis and the stress history for elastic analysis to determine the end point of the cycle. See T-1413 for the method of combining cycles for fatigue analysis. A single operational cycle may result in one or more strain cycles. Dynamic effects shall also be considered as strain cycles.

NH-3213.17 Fatigue Strength Reduction Factor.

Fatigue strength reduction factor is a stress intensification or a strain intensification factor which accounts for the effect of a local structural discontinuity (stress or strain concentration) on the fatigue strength. Factors currently exist only for cycles which do not involve significant creep effects.

NH-3213.18 Free End Displacement.

Free end displacement consists of the relative motions that would occur between a fixed attachment and connected piping if the two members were separated and permitted to move.

NH-3213.20 Deformation.

Deformation of a component part is an alteration of its shape or size.

NH-3213.21 Inelasticity.

Inelasticity is a general characteristic of material behavior in which the material does not return to its original shape and size after removal of all applied loads. Plasticity and creep are special cases of inelasticity.

NH-3213.22 Creep.

Creep is the special case of inelasticity that relates to the stress-induced time-dependent deformation under load. Small time-dependent deformations may occur after the removal of all applied loads.

NH-3213.23 Plasticity.

Plasticity is the special case of inelasticity in which the material undergoes time-independent nonrecoverable deformation.

NH-3213.24 Plastic Analysis.

Plastic analysis is that method which computes the structural behavior under given loads considering the plasticity characteristics of the materials, including strain hardening and the stress redistribution occurring in the structure.

NH-3213.25 Plastic Analysis - Collapse Load.

A plastic analysis may be used to determine the collapse load for a given combination of loads on a given structure. The following criteria for determination of the collapse load shall be used. A load-deflection or load-strain curve is plotted with load as the ordinate and deflection or strain as the abscissa. The angle that the linear part of the load deflection or load strain curve makes with the ordinate is called θ . A second straight line, hereafter called the collapse limit line, is drawn through the origin so that it makes an angle $\phi = \tan^{-1} (2 \tan \theta)$ with the ordinate. The collapse load is the load at the intersection of the load-deflection or load-strain curve and the collapse limit line. If this method is used, particular care should be given to assuring that the strains or deflections that are used are indicative of the load carrying capacity of the structure.

NH-3213.26 Plastic Instability Load.

The plastic instability load for members under predominantly tensile or compressive loading is defined as that load at which unbounded plastic deformation can occur without an increase in load. At the plastic tensile instability load, the true stress in the material increases faster than strain hardening can accommodate.

NH-3213.27 Limit Analysis.

Limit analysis is a special case of plastic analysis in which the material is assumed to be ideally plastic (nonstrain-hardening). In limit analysis the equilibrium and flow characteristics at the limit state are used to calculate the collapse load. The two bounding methods which are used in limit analysis are the lower bound approach, which is associated with a statically admissible stress field, and the upper bound approach, which is associated with a kinematically admissible velocity field. For beams and frames, the term *mechanism* is commonly used in lieu of *kinematically admissible velocity field*.

NH-3213.28 Limit Analysis - Collapse Load.

The methods of limit analysis are used to compute the maximum carrying load for a structure assumed to be made of ideally plastic material. If creep effects exist, then the influence of time-dependent deformations on the collapse load shall be considered.

NH-3213.29 Calculated Collapse Load - Lower Bound.

If, for a given load, any system of stresses can be found which everywhere satisfies equilibrium, and nowhere exceeds the material yield strength, the

Page 23

load is at or below the collapse load. This is the lower bound theorem of limit analysis which permits calculations of a lower bound to the collapse load. If creep effects exist, then the influence of time-dependent deformations on the collapse load shall be considered.

NH-3213.30 Plastic Hinge.

A plastic hinge is an idealized concept used in Limit Analysis. In a beam or a frame, a plastic hinge is formed at the point where the moment, shear, and axial force lie on the yield interaction surface. In plates and shells, a plastic hinge is formed where the generalized stresses lie on the yield surface.

NH-3213.31 Strain Limiting Load.

When a limit is placed upon a strain, the load associated with the strain limit is called the strain limiting load.

NH-3213.32 Test Collapse Load.

Test collapse load is the collapse load determined by tests according to the criteria given in Article II-1430 of Section

III.

NH-3213.33 Ratcheting.

Ratcheting is a progressive cyclic inelastic deformation. Total inelastic strain per cycle may vary from cycle to cycle in the most general situation. Stable ratcheting occurs when the net inelastic strain from a given load cycle is constant for subsequent cycles.

(a) Progressive incremental inelastic deformation can occur in a component that is subjected to cyclic variations of mechanical secondary stress, thermal secondary stress, or both in the presence of a primary stress.

(b) Where creep effects are significant, creep ratcheting can occur, even in the absence of plastic yielding. At least two mechanisms are involved in creep ratcheting. First, creep can alter the residual stresses and thus affect the time-independent behavior. Secondly, the time-dependent deformation can be enhanced because of the nonlinear interaction of primary and secondary stresses. This latter effect is referred to as *enhanced creep*.

NH-3213.34 Shakedown.

Shakedown is the absence of significant progressive, cyclic, inelastic deformation, or ratcheting (NH-3213.23). A structure shakes down if, after a few cycles of load application, the deformation stabilizes.

NH-3213.35 Design Information on the Nameplate.

Design Information on the Nameplate are the Design Temperature and the Design Pressure for the zone of the structure nearest the pressure relief device (or the top of the component if there are no pressure relief devices). The values for these parameters shall appear on the nameplate.

NH-3213.36 Use-Fraction.

Use-fraction is the material damage due to primary stresses expressed as a time ratio.

NH-3213.37 Fatigue Damage.

Fatigue damage is that part of the total material damage caused by cyclic deformation which is independent of time effects (e.g., stress holdtime, strain holdtime, frequency). The damage is expressed in terms of a cycle ratio.

NH-3213.38 Creep Damage.

Creep damage is that part of the total material damage caused by time exposure to steady and transient stresses at elevated temperatures, expressed as a time ratio. (Relaxation damage is a form of creep damage.)

NH-3213.39 Creep-Fatigue Interaction.

Creep-fatigue interaction is the effect of combined creep and fatigue on the total creep-fatigue damage accumulated at failure.

NH-3214 Stress Analysis

A detailed stress analysis of all major structural components shall be prepared in sufficient detail to show that each rule or limit of NH-3220 and NH-3230 is satisfied when the component is subjected to the loadings described in NH-3111. This detailed analysis shall become a part of the Stress Report (NCA-3550).

NH-3214.1 Elastic Analysis.

The analysis guidelines and methods in Article NB-3000 apply (NH-3211). As an aid to the evaluation of these elastic stresses, formulas and methods for the solution of certain recurring problems have been placed in Appendix A of Section III.

NH-3214.2 Inelastic Analysis.

When thermal and mechanical loadings are sufficiently severe to produce yielding and/or when thermal creep processes are active, inelastic design analysis may be required. The rules and limits of Appendix T were established with the expectation that inelastic analyses would sometimes be required, and that such analyses would be sufficiently comprehensive to predict significant behavioral features. Generally, this requires analysis of combined time-independent elastic-plastic material behavior and time-dependent creep behavior capable of predicting stresses, strains, and deformations as functions of time for specific thermal-mechanical load histories.

The constitutive equations, which describe the inelastic behavior, should reflect the following features when they have a significant influence on structural response: the effects of plastic strain hardening including cyclic loading effects and the hardening or softening which can occur with high temperature exposure; primary

Page 24

creep and the effects of creep strain hardening as well as softening (due to reverse loadings); and the effects of prior creep on subsequent plasticity, and vice versa.

The basis for choosing the selected methods and relations used should be included in the Design Report.

Since the rules and limits incorporate design factors and margins to account for material property variations and uncertainties, it is generally appropriate to use average stress-strain and creep data in inelastic design analyses. The buckling and instability limits of Appendix T are an exception; in T-1510(g) it is stated that the minimum expected stress-strain curve should be used.

NH-3214.3 Mechanical Properties.

The values of some mechanical properties needed for analysis are listed in Appendix I-14 and in Appendix T. Properties covered include:

- (a) isochronous stress-strain curves
- (b) yield strength
- (c) stress-to-rupture
- (d) modulus of elasticity
- (e) instantaneous and mean coefficients of thermal expansion

Other mechanical property relations used in the analysis shall be described and justified in the Stress Report.

NH-3215 Derivation of Stress Intensities

One requirement for the acceptability of a design (NH-3210) is that the calculated stress intensities shall not exceed specified allowable limits. These limits differ depending on the stress category (primary, secondary, etc.) from which the stress intensity is derived. This paragraph describes the procedure for the calculation of the stress intensities which are subject to the specified limits. The steps in the procedure are stipulated in the following subparagraphs.

(a) At the point on the component which is being investigated, choose an orthogonal set of coordinates such as tangential, longitudinal, and radial, and designate them by the subscripts, t , l , and r . The stress components in these directions are then designated σ_t , σ_l , and σ_r for direct stresses and τ_{lt} , τ_{lr} , and τ_{rt} for shearing stresses.

(b) Calculate the stress components for each type of loading to which the part will be subjected and assign each set of stress values to one or a group of the following categories:

- | | |
|-------|---|
| F | = peak stress components as defined in NH-3213.11. Tables NH-3217-1 and NH-3217-2 provide assistance in the determination of the category to which a stress should be assigned. |
| P_b | = primary bending stress components at a surface as defined in NH-3213.8 |

P_m, P_I

= average primary stress components as defined in NH-3213.8 and NH-3213.10

 Q

= secondary stress components as defined in NH-3212.9

It should be noted that each of the symbols for the above stress categories represents six scalar quantities corresponding to the six stress components, $\sigma_t, \sigma_l, \sigma_r, \tau_{lt}, \tau_{lr},$ and τ_{rt} . In the particular case of the six membrane stress components, each component shall be averaged across the thickness of the structural section.²

(c) For each category, calculate the algebraic sum of the σ_i values which result from the different types of loadings and similarly for the other five stress components. Certain combinations of the categories must also be considered.

(d) Translate the stress components for the $t, l,$ and r directions into principal stresses, $\sigma_1, \sigma_2,$ and σ_3 . (In many pressure component calculations, the $t, l,$ and r directions may be so chosen that the shearing stress components are zero and $\sigma_1, \sigma_2,$ and σ_3 are identical to $\sigma_t, \sigma_l,$ and σ_r .)

(e) Calculate the stress differences $S_{12}, S_{23},$ and S_{31} from the relations:

$$S_{12} = \sigma_1 - \sigma_2$$

$$S_{23} = \sigma_2 - \sigma_3$$

$$S_{31} = \sigma_3 - \sigma_1$$

The stress intensity, S , is the largest absolute value of $S_{12}, S_{23},$ and S_{31} .

NH-3216 Derivation of Stress Differences and Strain Differences

The ability of the component to withstand the specified cyclic operation without creep-fatigue failure shall be determined as in NH-3250. The evaluation shall demonstrate, by evaluating the stresses and strains at selected points of the components, that the combined creep-fatigue damage is everywhere within design limits. Only the stress and strain differences due to the operational cycles as specified in the Design Specifications need be considered.

NH-3217 Classification of Stresses

Tables NH-3217-1 and NH-3217-2 provide assistance in the determination of the category to which a stress

Page 25

_____ should be assigned. For portions of the component not exposed to elevated temperature service, the classification or _____ category may be selected as in NB-3000. Pages 26-26

TABLE NH-3217-1
CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES

Vessel Component	Location	Origin of Stress	Type of Stress	Classification
Cylindrical or spherical shell	Shell plate remote from discontinuities	Internal pressure	General membrane Gradient through plate thickness	P_m Q
		Axial thermal gradient	Membrane Bending	Q [Note (1)] Q
	Junction with head or flange	Internal pressure	Membrane Bending	P_L Q [Note (2)]
Any shell or head	Any section across entire vessel	External load or moment, or internal pressure	General membrane averaged across full section. Stress component perpendicular to cross section	P_m
		External load or moment	Bending across full section. Stress component perpendicular to cross section	P_m
	Near nozzle or other opening	External load or moment, or internal pressure	Local membrane Bending Peak (fillet or corner)	P_L Q F
	Any location	Temp. diff. between shell and head	Membrane Bending	Q [Note (1)] Q
Dished head or conical head	Crown	Internal pressure	Membrane Bending	P_m P_b
	Knuckle or junction to shell	Internal pressure	Membrane Bending	P_L [Note (3)] Q
Flat head	Center region	Internal pressure	Membrane Bending	P_m P_b
	Junction to shell	Internal pressure	Membrane Bending	P_L Q [Note (2)]
Perforated head or shell	Typical ligament in a uniform pattern	Pressure	Membrane (Av. thru cross section) Bending (Av. thru width of lig., but gradient thru plate) Peak	P_m P_b F
	Isolated or atypical ligament	Pressure	Membrane Bending Peak	Q F F

(Table continued on next page)

TABLE NH-3217-1 CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES

**TABLE NH-3217-1 (CONT'D)
CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES**

Vessel Component	Location	Origin of Stress	Type of Stress	Classification
Nozzle (NH-3227.5)	Within the limits of reinforcement defined by NH-3334	Pressure and external loads and moments including those attributable to restrained free end displacements of attached piping	General membrane Bending (other than gross structural discontinuity stresses) averaged through nozzle thickness	P_m P_m
	Outside the limits of reinforcement defined by NH-3334	Pressure and external axial, shear, and torsional loads other than those attributable to restrained free end displacements of attached piping	General membrane stresses	P_m
		Pressure and external loads and moments other than those attributable to restrained free end displacements of attached piping	Membrane Bending	P_L P_b

NOTES:

- (1) These classifications may be modified for purposes of certain criteria in Appendix T.
- (2) If the bending moment at the edge is required to maintain the bending stress in the middle to acceptable limits, the edge bending is classified as P_b . Otherwise, it is classified as Q .
- (3) Consideration must also be given to the possibility of wrinkling and excessive deformation in vessels with large diameter-to-thickness ratio.
- (4) Consider possibility of thermal stress ratched (see NH-3250).
- (5) Equivalent linear stress is defined as the linear stress distribution which has the same net bending moment as the actual stress distribution.

(3) Analysis is not required when reinforced in accordance with NH-3643.

TABLE NH-3217-2 CLASSIFICATION OF STRESS INTENSITY IN PIPING, TYPICAL CASES

NH-3220 DESIGN RULES AND LIMITS FOR LOAD CONTROLLED STRESSES IN STRUCTURES OTHER THAN BOLTS

NH-3221 General Requirements

(a) The rules for design against failure from load controlled stresses are illustrated in Fig. NH-3221-1 and are explained in NH-3220. The allowable stress intensity values used in NH-3220 are listed in Tables 2A and 2B of Section II, Part D, Subpart 1 and Tables I-14.0. Note that the strain, deformation, and fatigue limits of NH-3250 require analyses beyond those required by the rules of NH-3220.

(b) The stress intensity limits used in Fig. 3221-1 and throughout this Subsection are defined for base metal and at weldments as follows:

(1) *Base Metal*

S_m

= the lowest stress intensity value at a given temperature among the time-independent strength quantities which are

defined in Section II, Part D as criteria for determining S_m ; in Subsection NH, the S_m values are extended to elevated temperatures by using the same criteria.

= the allowable limit of general primary membrane stress intensity to be used as a reference for stress calculations for the actual service life and under the Level A and B Service Loadings; the allowable values are shown in Figs. I-14.3 and in Tables I-14.3. The S_{mt} values are the lower of two stress intensity values, S_m (time-independent) and S_t (time-dependent).

S_{mt}

Page 28

Page 29

FIG. NH-3221-1 FLOW DIAGRAM FOR ELEVATED TEMPERATURE ANALYSIS

FIG. NH-3221-1 FLOW DIAGRAM FOR ELEVATED TEMPERATURE ANALYSIS

S_o = the maximum allowable value of general primary membrane stress intensity to be used as a reference for stress calculations under Design Loadings. The allowable values are given in Table I-14.2. [The values correspond to the S values given in Section II, Part D, Subpart 1, Table 1A, except for a few cases at lower temperatures where values of S_{mt} (defined below and given in Tables I-14.3) at 300,000 hours exceed the S values. In those limited cases, S_o is equal to S_{mt} at 300,000 h rather than S .]

S_t = a temperature and time-dependent stress intensity limit; the data considered in establishing these values are obtained from long-term, constant load, uniaxial tests. For each specific time, t , the S_t values shall be the lesser of: (1) 100% of the average stress required to obtain a total (elastic, plastic, primary, and secondary creep) strain of 1%; (2) 80% of the minimum stress to cause initiation of tertiary creep; and (3) 67% of the minimum stress to cause rupture.

S_y = the yield strength of a material at a given temperature

(2) Weldments

S_{mt} = the allowable limit of general primary membrane stress intensity, and shall be taken as the lower of the S_{mt} values from Tables I-14.3, or:

$$0.8 S_r \times R$$

S_t = temperature and time-dependent stress intensity limit at a weldment, and shall be taken as the lower of the tabulated S_t values from Tables I-14.4, or:

$$0.8 S_r \times R$$

where

R = the appropriate ratio of the weld metal creep rupture strength to the base metal creep rupture strength from Tables I-14.10. The lowest S_t value of the adjacent base metals shall be utilized for the weldment.

S_r = the expected minimum stress-to-rupture strength given in Tables I-14.6

NH-3222 Design and Service Limits

NH-3222.1 Design Limits.

The stress calculations required for the analysis of Design Loadings (NH-3113.1) shall be based on a linearly elastic material model. The calculated stress intensity values shall satisfy the limits of (a) and (b) below.

(a) The general primary membrane stress intensity, derived from P_m , shall not exceed S_o^4

$$(1) P_m \leq S_o$$

(b) The combined primary membrane plus bending stress intensity, derived from P_L and P_b , shall not exceed $1.5 S_o$:

$$(2) (P_L + P_b) \leq (1.5) S_o$$

Note that the local primary membrane stress, P_L , includes the general primary membrane stress, P_m . As in Subsection NB, the left-hand side of Eq. (2) does not represent a simple algebraic combination since P_L and P_b may each represent as many as six quantities [NH-3215(b)].

(c) External pressure and other compression inducing loadings shall be investigated for adequate buckling strength, using the limits of NB-3133 or other limits and time-independent factors permitted under NH-3252.

NH-3222.2 Level A Service Limits.

The stress intensity limits for Level A Service Limits (NH-3113.3) also apply to the stresses under both Level A and B Service Loadings. The limits for both are given in NH-3223.

NH-3223 Level A and B Service Limits

The stress calculations required for the analysis of Level A and B Service Loadings (NH-3113.4) are based on a linearly elastic material model. The calculated stress-intensity values shall satisfy the conditions of (a) through (f) below.

(a) The general primary membrane stress intensity, derived from P_m for Level A and B Service Loadings, shall not exceed S_{mt} :

$$(3) P_m \leq S_{mt}$$

⁴ To satisfy Eq. (1) for straight cylindrical shapes, the minimum wall thickness may be calculated by the equations in PG-27 of Section I, Power Boilers, using S_o in place of S .

where S_{mt} is determined for the time, t , corresponding to the total duration of the particular loading during

Page 30

the entire service life, and for temperature, T , corresponding to the maximum wall averaged temperature that occurs during the particular loading event.

(b) When time, t , [in (a) above] is less than the total specified service life of the component, the cumulative effect of all the loadings shall be evaluated by the use-fraction sum in NH-3224(b). In addition, it is permissible and often advantageous to subdivide a loading history into several load levels and into several temperatures at any given load level.

(c) The combined primary membrane plus bending stress intensities, derived from P_L and P_b for Level A and B Service Loadings, shall satisfy the following limits with:

$$(4) P_L + P_b \leq K S_m$$

$$(5) P_L + P_b / K_t \leq S_t$$

The factor K_t accounts for the reduction in extreme fiber bending stress due to the effect of creep. The factor is given by:

$$(6) K_t = (K + 1) / 2$$

The factor, K , is the section factor for the cross section being considered. It is the ratio of the load set producing a fully plastic section to a load set producing initial yielding of the extreme fiber of the cross section. In evaluating the initial yield and fully plastic section capabilities, the ratios of each individual load in the respective load set to each other load in that load set shall be the same as the respective ratios of the individual loads in the specified service load set. Values of K for various sections are given in Table A-9521(b)-1 of Appendix A of Section III.

(d) In evaluating across-the-wall bending of shell type structures, $K = 1.5$ (for rectangular sections) shall be used. Thus, for across-the-wall shell bending, $K_t = 1.25$ in Eq. (6). Note that the classification of stresses of primary membrane or primary bending for use with these section factors shall be consistent with the specific rules for the component type (see NH-3300 to NH-3600).

(e) In Eq. (5), the S_t value is determined for the time, t , corresponding to the total duration of the combined stress intensity derived from P_L and P_b / K_t and the maximum wall averaged temperature, T , during the entire service life of the component.

(f) When t is less than the total service life of the component, the cumulative effect of all $[P_L + (P_B/K_T)]$ loadings shall be evaluated by the use-fraction sum of NH-3224(d). It is permissible and often advantageous to separate a loading history into several load levels and into several temperatures at any given load level.

(g) Under all conditions where a bending loading occurs across a section, the propensity for buckling of that part of the section in compression shall be investigated under the requirements of NH-3250.

NH-3224 Level C Service Limits

The stress calculations required for Level C Service Loadings analysis are based on a linearly elastic material model. The calculated stress intensity values shall satisfy the conditions of (a) through (d) below.

(a) The general primary membrane stress intensity, derived from P_m for Level C Service Loadings, shall not exceed the smaller of $1.2 S_m$ and $1.0 S_t$:

$$P_m \leq \begin{cases} 1.2 S_m \\ 1.0 S_t \end{cases} \quad (7)$$

(7)

(b) In addition, the use-fraction sum associated with the general primary membrane stresses for all increments of primary loadings during Levels A, B, and C Loadings shall satisfy the following requirements:

$$\sum_i \left(\frac{t_i}{t_{im}} \right) \leq B \quad (8)$$

(8)

where

B

= use-fraction factor and is equal to 1.0 [or less if so specified in the Design Specifications (NCA-3250)]

t_i

= the total duration of a specific loading, P_{mT} , at elevated temperature, T , during the entire service life of the component.

Note that

$$\sum_i (t_i)$$

is that part of the component service life at elevated temperatures (i.e., temperatures above values governed by the rules of Subsection NB as explained in NH-3211).

t_{im}

= maximum allowed time under the load stress intensity, S_p , as determined from a graph of S_t -vs-time (see Figs. I-14.4.)

The use of Figs. I-14.4 for determining t_{im} for two loading conditions at two different temperatures is shown schematically in Fig. NH-3224-1. In Fig. NH-3224-1, P_{mi} ($i = 1, 2, 3$, etc.) represents the calculated membrane stress intensity for the loading condition and temperature in question; and T_i represents the maximum local wall averaged temperature during t_i . Note that it may be desirable to consider that a given stress intensity,

Page 31

P_{mi} acts during several time periods, t_p , in order to take credit for the fact that the temperature varies with time.

FIG. NH-3224-1 USE-FRACTIONS FOR MEMBRANE STRESS

FIG. NH-3224-1 USE-FRACTIONS FOR MEMBRANE STRESS

(c) The combined primary membrane plus bending stress intensities, derived from P_L and P_b for Level C Service Loadings, shall satisfy the following limits, with $1.0 < K \leq 1.5$:

$$(9) P_L + P_b \leq 1.2 K S_m$$

$$(10) P_L + P_b / K_t \leq S_t$$

where K_t is defined as in NH-3223(c).

(d) In addition, the sum of the use-fractions associated with the primary membrane plus bending stresses for all increments of primary loadings during Levels A, B, and C Service Loadings shall not exceed the value, 1.00:

$$\sum_i \left(\frac{t_i}{t_{ib}} \right) \leq 1.00 \quad (11)$$

(11)

where

t_i

= the total duration of the loading at temperature, T_i ; and

t_{ib}

= the time value determined by entering Figs. I-14.4 at a value of stress equal to $P_L + P_b / K_p$ as shown in Fig. NH-3224-2.

FIG. NH-3224-2 USE-FRACTIONS FOR MEMBRANE PLUS BENDING STRESS

FIG. NH-3224-2 USE-FRACTIONS FOR MEMBRANE PLUS BENDING STRESS

NH-3225 Level D Service Limits

The rules of this paragraph may be used in the evaluation of components subjected to loads specified as Level D Service Loadings.

(a) The rules in NH-3225 (and in Appendix F of Section III) shall be applied in all instances unless alternative or supplementary criteria, as required by public health and safety considerations for specific components or systems, are defined in, and made applicable by, the Owner's Design Specifications [NCA-3250]. The type of analysis (elastic or inelastic) used by the system designer shall be indicated in the Design Specifications (see F-1322.1).

(b) The general primary membrane stress intensity, derived from P_m for the Level D Service Loadings, shall not exceed the smaller of $0.67 S_p$, $0.8 RS_p$, and one of the Level D Service Limits in Appendix F of Section III:

$$P_m \leq \begin{cases} \text{Limit in Appendix F for } P_m \\ 0.67 S_r \\ 0.8 RS_r \end{cases} \quad (12)$$

(12)

where

R

= the appropriate ratio of the weld metal creep fatigue strength to the base metal strength from Tables I-14.10

S_r

= the expected minimum stress-to-rupture in time t taken from Figs. I-14.6

(c) In addition, the use-fraction sum associated with the general primary membrane stresses that arise from all Service Loadings, shall satisfy the requirement:

Page 32

$$\sum_i \left(\frac{t_i}{t_{ir}} \right) \leq B_r$$

where

B_r

= use-fraction factor and is equal to 1.0 (or less if so specified in the Design Specifications [NCA-3250])

t_i

= the total duration of a specific loading, P_{mi} , at elevated temperature, T_i , during the entire service life of the component. Note that

$$\sum_i (t_i)$$

is that part of the component service life at elevated temperatures (i.e., temperatures above values governed by the rules of Subsection NB, as explained in NH-3211).

t_{ir}

= maximum allowed time under the load stress intensity $1.5 P_{mi}$ for base metal or, for weldments, the higher of $1.5 P_{mi}$ ($1.25/R$) P_{mi} . The allowable time under load is determined from the graph of minimum stress-to-rupture vs time (see Figs. I-14.6).

The use of Figs. I-14.6 for determining t_{ir} for two loading conditions at two different temperatures is shown schematically in Fig. NH-3224-1. In Fig. NH-3224-1, $1.5 P_{mi}$ ($i = 1, 2, 3$, etc.) represents 1.5 times the calculated membrane stress intensity for the loading condition and temperature in question, and T_i represents the maximum local wall averaged temperature during t_i . Note that it may be desirable to consider that a given stress intensity acts during several time periods, t_p , in order to take credit for the variation of temperature with time.

(d) The combined primary membrane plus bending stress intensities, derived from P_L and P_b , shall satisfy the following limits, with $1.0 \leq K \leq 1.5$, and Level D Service Limits in Appendix F for $P_L + P_b$:

$$P_L + P_b/K_t \leq \begin{cases} 0.67 S_r \\ 0.8 RS_r \end{cases} \quad (13)$$

(13)

where K_t is defined in NH-3223(c).

(e) In addition, the sum of the use-fraction associated with the primary membrane plus bending stresses that arise from all Service Loadings, shall not exceed the value of 1.00:

$$\sum_i \left(\frac{t_i}{t_{ibr}} \right) \leq 1.00$$

where

t_i

= the total duration of loading at temperature, T_i

t_{ibr}

= the time value determined by entering Figs. I-14.6 at a value of stress equal to $1.5 (P_L + P_b/K_t)$ for base metal or higher of $1.5 (P_L + P_b/K_t)$ and $1.25 (P_L + P_b/K_t)/R$ for weldments as shown in Fig. NH-3224-2

(f) For the purpose of Section III, Appendix F calculations, the yield strength and tensile strength values shall be defined as follows:

(1) Yield strength values shall be the product of the value shown in Table I-14.5 and the strength reduction factor shown in Tables NH-3225-2, NH-3225-3A, and NH-3225-3B.

(2) Tensile strength values shall be the product of the value shown in Table NH-3225-1 and the strength reduction factor shown in Tables NH-3225-2, NH-3225-3A, and NH-3225-3B, where the strength reduction factor is selected as a function of the accumulated time-temperature history to which the component has been exposed prior to the event under analysis. Where a component has been exposed to a varying temperature history, the reduction factor employed shall be determined by assuming that the component has operated at the maximum temperature throughout its prior operational life (exclusive of Level D Service Condition.)

NH-3226 Pressure Testing Limitations

During any static pressure testing, the following limits shall not be exceeded in any structural part:

- (a) The general primary membrane stress intensity shall not exceed 90% of the tabulated yield strength at temperature;
- (b) The primary membrane plus bending stress intensity shall not exceed 135% of the tabulated yield stress at temperature;
- (c) The external pressure shall not exceed 135% of the maximum pressure allowed by the design rules of NH-3250.

NH-3227

The following deviations from the basic stress limits are provided to cover special operating conditions or configurations. Some of these deviations are more restrictive, and some are less restrictive, than the basic stress limits. In cases of conflict between these requirements and the basic stress limits, the rules of NH-3227 take precedence for the particular situations to which they apply.

NH-3227.1 Bearing Loads

(a) The average bearing stress for resistance to crushing under the maximum load, experienced as a result

Page 33

of load categories other than Level D Service Loading, shall be considered.

1,450	23.1	24.7	29.7	...	...
1,500	19.3	20.7	24.8	...	...

GENERAL NOTES:

- The tabulated values of tensile strength and yield strength are those which the Committee believes are suitable for use in design calculations required by this Section. At temperatures above room temperature, the values of tensile strength tend toward an average or expected value which may be as much as 10% above the tensile strength trend curve adjusted to the minimum specified room temperature tensile strength. At temperatures above room temperature, the yield strength values correspond to the yield strength trend curve adjusted to the minimum specified room temperature yield strength. Neither the tensile strength nor the yield strength values correspond exactly to either *average* or *minimum* as these terms are applied to a statistical treatment of a homogeneous set of data.
- Neither the ASME Material Specifications nor the rules of this Section required elevated temperature testing for tensile or yield strengths of production material for use in Code components. It is not intended that results of such tests, if performed, be compared with these tabulated tensile and yield strength values for ASME Code acceptance/rejection purposes for materials. If some elevated temperature test results on production material appear lower than the tabulated values by a large amount (more than the typical variability of material and suggesting the possibility of some error), further investigation by retest or other means should be considered.

TABLE NH-3225-1 TENSILE STRENGTH VALUES (S_u), ksi

The average bearing stress for Service Levels A, B, and C shall be limited to the lesser of:

- (1) the tabulated yield strength at the Service Temperature; or
 - (2) the stress at 0.2% offset strain as obtained from the isochronous stress-strain curve for the temperature of service and for the time duration equal to the total service life the component is expected to spend at temperatures greater than those listed in Tables 2A and 2B of Section II, Part D, Subpart 1.
- (b) For clad surfaces, the properties of the base metal may be used if, when calculating the bearing stress, the bearing area is taken as the lesser of the actual contact area or the area of the base metal supporting the contact surface.

TABLE NH-3225-3B TENSILE STRENGTH REDUCTION FACTORS FOR 2¹/₄Cr-1Mo

(c) When bearing loads are applied near free edges, such as at a protruding edge, the possibility of a shear failure shall be considered. The average shear stress shall be limited to $0.6 S_{mt}$ in the case of load controlled stresses. For clad surfaces, if the configuration or thickness is such that a shear failure could occur entirely within the clad material, the allowable shear stress for the cladding shall be determined from the properties of the equivalent wrought material. If the configuration is such that a shear failure could occur across a path that is partially base metal and partially clad material, the allowable shear stresses for each material shall be used when evaluating the combined resistance to this type of failure.

NH-3227.2 Pure Shear

(a) The average primary shear stress across a section loaded in pure shear (for example, keys, shear rings, screw threads), experienced as a result of any loading categories other than Level D Service Loadings, shall be limited to $0.6 S_{mt}$

(b) The maximum primary shear stress, experienced as a result of any loading categories other than Level D Service Loadings, exclusive of stress concentration at the periphery of a solid circular section in torsion, shall be limited to $0.8 S_{mt}$

NH-3227.3 Progressive Distortion of Nonintegral Connections.

Screwed on caps, screwed in plugs, shear

Page 35

ring closures, and breech lock closures are examples of nonintegral connections which are subject to failure by bell mouthing or other types of progressive deformation. If any combination of applied loads produces yielding, such joints are subject to ratcheting because the mating members may become loose at the end of each complete operational cycle and start the next cycle in a new relationship with each other, with or without manual manipulation. Additional distortion may occur in each cycle so that interlocking parts, such as threads, can eventually lose engagement. Such nonintegral connections shall not be used where service temperatures are expected to exceed those associated with allowable stress intensity values for the specific materials as shown in Tables 2A and 2B of Section II, Part D, Subpart 1.

NH-3227.4 Triaxial Stresses.

The algebraic sum of the three primary principal stresses ($\sigma_1 + \sigma_2 + \sigma_3$) shall not exceed four times the tabulated value of S_{mt}

NH-3227.5 Nozzle Piping Transition.

The P_m classification of stresses resulting from pressure, external loads, and moments is applicable for that length of nozzle which lies within the limits of reinforcement given by NB-3334, whether or not nozzle reinforcement is provided. Beyond the limits of reinforcement, a P_m classification shall be applied to the general primary membrane stress intensity averaged across the section (not thickness) resulting from combined pressure and external mechanical loads; a P_L or $P_L + P_b$ classification shall be respectively applied to local primary membrane or local primary membrane plus bending stress intensities that result from design pressure and external mechanical loads; and a $P_L + P_b + Q$ classification shall be applied to primary plus secondary stress intensities resulting from all loads including external load or moment attributable to restrained free end displacement of the attached pipe.

NH-3227.7 Requirements for Specially Designed Welded Seals

(a) Welded seals, such as omega and canopy seals (NB-4360), shall be designed to meet the pressure-induced general primary membrane stress intensity limits specified in Subsection NH for their materials of fabrication. Note that the general primary membrane stress intensity varies around the toroidal cross section.

(b) All other membrane and bending stress intensities developed in the welded seals may be considered as secondary stress intensities or peak stress intensities, as appropriate.

NH-3227.8 Cladding.

The rules of (a) through (d) below apply to the analysis of clad components constructed of material under this Subsection.

(a) *Load Controlled Stresses.* No structural strength shall be attributed to the cladding in satisfying the load controlled stress limits in NH-3200.

(b) *Design Dimensions.* The dimensions stipulated in (1) and (2) below shall be used in the design of the component.

(1) For components subjected to internal pressure, the inside diameter shall be taken at the nominal inner face of the cladding;

(2)

metal.

(c) *Deformation Controlled Quantities.* No structural strength shall be attributed to the cladding in satisfying requirements on buckling instability. However, the cladding shall be considered in all other calculations related to satisfying limits on deformation controlled quantities.

(d) *Bearing Stresses.* In satisfying (a), the presence of cladding shall be included.

NH-3230 STRESS LIMITS FOR LOAD CONTROLLED STRESSES ON BOLTS

NH-3231 General Requirements

(a) Elevated temperature components which contain bolts not exposed to elevated temperature service may be designed using the materials, design methods, and design limits of Subsection NB (NB-3230 and Appendix E of Section III).

(b) Bolts which are to experience elevated temperature service shall comply with the requirements of NH-3230.

NH-3232 Design Limits for Bolts at Elevated Temperatures

(a) The number and cross-sectional area of bolts required to resist the design pressure may be determined in accordance with the procedures of Appendix E of Section III, using the larger of the bolt loads given by the equations of Appendix E of Section III as a design mechanical load. The reference allowable bolt design stress intensity values shall be the S_o values given in Table I-14.12 for bolting materials.

(b) When the seal is effected by a seal weld and no gasket is used, the gasket factor, m , and the minimum design seating stress, y , may be taken as zero.

Page 36

(c) When gaskets are used for preservice testing only, the design shall be acceptable if the requirements of (a) above are satisfied using $m = y = 0$, and the requirements of NH-3233 are satisfied using the appropriate m and y factors for the test gasket.

NH-3233 Level A and B Service Limits for Bolts at Elevated Temperatures

NH-3233.1 Average Stress.

The maximum value of stress due to pressure loading, averaged across the bolt cross section and neglecting stress concentrations, shall not exceed the S_{mt} stress values of Table I-14.13C. The rules of NH-3232 shall apply except for the S_{mt} values replacing S_o values.

NH-3233.2 Maximum Stress in the Cross Section.

The maximum values for service stresses (averaged across the bolt cross section and neglecting stress concentrations), such as those produced by a combination of preload, pressure, and thermal expansion, shall not exceed two times the S_{mt} values of Figs. I-14.13 unless the design lifetime is divided into two or more loading periods and the possibility of creep rupture due to membrane stresses is guarded against by satisfying the use-fraction rule described in NH-3224(b), with the use-fraction factor, B , set equal to 0.5.⁵ Stress intensity, rather than maximum stress, shall be limited to this value when bolts are tightened by devices which result in residual torsion stresses. Residual torsion stresses are minimized by devices such as heaters and stretchers.

NH-3233.3 Maximum Stress in the Bolt Periphery.

The maximum value of service stress at the periphery of the bolt cross section (resulting from tension-plus-bending and neglecting stress concentrations) shall not exceed the lesser of three times the S_{mt} values in Figs. I-14.13 or $K_t S_t$ unless the design lifetime is divided into two or more loading periods and the possibility of creep rupture due to bending stresses is guarded against by satisfying the use-fraction rule described in NH-3224(d), but with the use-fraction set at 0.67 instead of 1.0.⁵ Stress intensity, rather than maximum stress, shall be limited to this value when bolts are tightened by devices which result in residual torsion stresses. Residual torsion stresses are minimized by devices such as heaters

and stretchers.

NH-3233.4 Nonductile Fracture.

The rules of NH-3241 shall apply to bolts.

5 S_t values to be used are twice those given in Table I-14.13C.

NH-3234 Level C Service Limits

The limits of NH-3233 shall apply to primary loads in bolts.

NH-3235 Level D Service Limits

The rules of NH-3225 shall apply to primary loads in bolts.

NH-3240 SPECIAL REQUIREMENTS FOR ELEVATED TEMPERATURE COMPONENTS

NH-3241 Nonductile Fracture

(a) A portion of the Stress Report (NCA-3550) shall justify the ability of the component to withstand the expected service conditions without undergoing nonductile fracture. Even though components are not expected to fail by nonductile fracture while at elevated temperatures, the stress relaxation occurring under elevated temperature conditions will often lead to high residual stresses during the portion of the operational cycle with lowest temperatures. For loading times, stresses, and temperatures where creep effects are not significant (NH-3211), an acceptable procedure for nonductile failure prevention is given in Appendix G of Section III for ferritic materials. When Appendix G of Section III is not applicable, the fracture analysis shall consider the anticipated stress level and flaw size, and compare these conditions with the fracture toughness of the material in the flaw region and at the appropriate temperature.

(b) The above justification requirements do not apply to Type 304 SS, Type 316 SS, or Alloy 800H, unless the fabrication effects substantially alter the fracture characteristics of these materials in such a manner that nonductile fracture becomes a plausible failure mode. The Design Specifications shall state when and how environmental effects shall be considered for nonductile fracture behavior in these materials.

NH-3250 LIMITS ON DEFORMATION CONTROLLED QUANTITIES

NH-3251 General Requirements

The strains and deformation resulting from the specified operating conditions shall be evaluated. This evaluation shall include the effects of ratcheting, the interaction of creep and fatigue, and the possibility of buckling and structural instability. The N Certificate Holder shall

Page 37

document, as a portion of the Design Report (NCA-3550), what effects and conditions were considered the final analysis procedures, the evaluation criteria, and the conclusions of the evaluation.

NH-3252 Criteria

It is the responsibility of the Owner to define the acceptability criteria to be applied as buckling, strain, deformation, and fatigue limits in the Design Specifications (NCA-3250). The acceptability criteria and material properties contained in Appendix T may be used. However, alternative criteria may be applied by the Manufacturer subject to approval by the Owner. The Owner's approval shall be indicated by incorporating the alternative criteria into the Design Specifications.

NH-3300 VESSEL DESIGNS

NH-3310 GENERAL REQUIREMENTS

NH-3311 Acceptability

(a) The requirements for acceptability of Class 1 vessel design are stated in NH-3111.1.

(b) In cases of conflict between this Subarticle and the rules of Subarticles NH-3100 and NH-3200, the requirements of NH-3300 shall govern.

NH-3330 OPENINGS AND REINFORCEMENT

NH-3331 General Requirements for Openings

(a) For vessels or parts thereof which meet the requirements of NH-3330, the analysis limits of NH-3220 related to load controlled stresses need not be demonstrated in the vicinity of the openings. However, the deformation controlled limits (NH-3250) shall be satisfied in the vicinity of any opening exposed to conditions where creep effects are significant [NH-3211(c)].

(b) Openings (for nozzle, branch, and piping connections) using deposited weld metal as reinforcement, as shown in Fig. NB-4244(c)-1, shall be limited to nominal diameters of 4 in. or less.

(c) If it is shown by analysis that all of the requirements of NH-3200 have been met for the structural material near an opening, then the rules of NH-3332 through NH-3339 are waived.

NH-3332 Reinforcement Requirements for Openings in Shells and Formed Heads

The rules of NB-3332 shall apply except that:

(a) The $1.1 S_m$ limit, which defines a locally stressed area, shall be replaced by $1.1 S_{mt}$. The S_{mt} value shall correspond to the time equal to the service life of the vessel.

(b) t_r is the thickness which meets the requirements for primary membrane and primary membrane plus bending under Level A and B Service Loadings.

NH-3333 Reinforcement Required for Openings in Flat Heads

The requirements of NB-3333 shall apply, with the t_r defined as in NH-3332.

NH-3334 Limits of Reinforcement

The requirements of NB-3334 shall apply.

NH-3335 Metal Available for Reinforcement

The requirements of NB-3335 shall apply except that subparagraph (a) is replaced by:

(a) metal forming a part of the vessel wall which is in excess of t_r (as defined in NH-3332) and is exclusive of corrosion allowance;

NH-3336 Strength of Reinforcing Material

(a) Material used for nozzle wall reinforcement shall be made of the same alloy type as that of the vessel wall, and the strength properties shall be assumed equivalent to those of the vessel wall material.

(b) When the deposited weld metal is used as reinforcement, the coefficients of thermal expansion of the base metal, the weld metal, and the nozzle shall not differ by more than 15% of the lowest coefficient involved.

NH-3337 Attachment of Nozzles and Other Connections

NH-3337.1 General Requirements.

Nozzles and other Category D connections (NH-3351) shall be attached to the shell or head of the vessel by one of the methods provided in NH-3352.

NH-3337.2 Full Penetration Welded Nozzles.

Full penetration nozzle welds, as shown in Figs. NB-4244(a)-1, NB-4244(b)-1, NB-4244(c)-1, and NB-4244(e)-1, may be used (except as otherwise provided in NH-3337.3)

Page 38

for the purpose of achieving continuity of metal and facilitating the required radiographic examination. When all or part of the required reinforcement is attributable to the nozzle, the nozzle shall be attached by full penetration welds through either the vessel or the nozzle thickness, or both.

NH-3337.3 Partial Penetration Welded Nozzles

(a) Partial penetration welds, as shown in Figs. NB-4244(d)-1 and NB-4244(d)-2, are allowed only for attachments on which there are essentially no piping reactions. Examples of such attachments include control rod housings, pressurized heater attachments, and openings for instrumentation.

(b) Earthquake loadings normally need not be considered in determining whether piping reactions are substantial. However, such loadings shall be considered if significant creep effects can occur at the nozzle.

(c) For such attachments, all reinforcement shall be integral with the portion of the vessel penetrated. Partial penetration welds shall be of sufficient size to develop the full strength of the attachment.

(d) Nozzles attached by partial penetration welds shall have an interference fit or a maximum diametral clearance between the nozzle and the vessel penetration of:

- (1) 0.010 in. for $d \leq 1$ in.
- (2) 0.020 in. for $1 \text{ in.} < d \leq 4$ in.
- (3) 0.030 in. for $d > 4$ in.

where d is the outside diameter of the nozzle.

(e) The ratio of nominal nozzle diameter to that of the main vessel shall be 0.1 or less.

(f) If significant creep effects occur in the vicinity of the nozzle, the use of partial penetration welds shall be restricted to nozzles with nominal diameters of 1 in. (25 mm) or less.

NH-3338 Pressure Stresses in Openings for Fatigue Evaluation

The rules of NB-3338 apply only to stress, temperature, and time conditions in which creep phenomena are insignificant [NH-3211(c)]. For conditions where creep effects are significant, the rules of NH-3250 apply. Hence, openings not exposed to elevated temperatures are meeting the fatigue requirements of Subsection NB.

NH-3339 Alternative Rules for Nozzle Design

The rules of NB-3339 apply only when the elastic model analysis of NH-3338 is also applicable.

NH-3350 DESIGN OF WELDED CONSTRUCTION

NH-3351 Welded Joint Category

The term *Category*, as used herein, defines the location of a joint in a vessel, but not the type of joint. The categories established by this paragraph are for use in specifying special requirements regarding joint type and degree of examination for certain welded pressure joints. Since these special requirements, which are based on service, material, and thickness, do not apply to every welded joint, only those joints to which special requirements apply are included in the categories. The special requirements will apply to joints of a given category only when specifically so stated. The joints included in each category are designated as joints of Categories A, B, C, and D. Figure NH-3351-1 illustrates typical joint locations included in each category.

NH-3351.1 Category A.

Category A comprises longitudinal welded joints within the main shell, communicating chambers,⁶ transitions in diameter, or nozzles; any welded joint within a sphere, within a formed or flat head, or within the side plates⁷ of a flat sided vessel; and circumferential welded joints connecting hemispherical heads to main shells, to main shells, to transitions in diameters, to nozzles, or to communicating chambers.⁶

NH-3351.2 Category B.

Category B comprises circumferential welded joints within the main shell, communicating chambers,⁶ nozzles, or transitions in diameter, including joints between the transition and a cylinder at either the large or small end; circumferential welded joints connecting formed heads other than hemispherical to main shells, to transitions in diameter, to nozzles, or to communicating chambers.⁶

NH-3351.3 Category C.

Category C comprises welded joints connecting flanges, Van Stone laps, tube-sheets, or flat heads to main shell, to formed heads, to transitions in diameter, to nozzles, or to communicating chambers⁶ any welded joint connecting one side plate⁷ to another side plate of a flat sided vessel.

NH-3351.4 Category D.

Category D comprises welded joints connecting communicating chambers⁶ or nozzles to main shells, to spheres, to transitions in diameter, to heads or to flat sided vessels, and those joints connecting nozzles to communicating chambers.

⁶ Communicating chambers are defined as appurtenances to the vessel which intersect the shell or heads of a vessel and form an integral part of the pressure retaining closure, e.g., sumps.

⁷ Side plates of a flat-sided vessel are defined as any of the flat plates forming an integral part of the pressure retaining enclosure.

For nozzles at the small end of a transition in diameter, see Category B.

**FIG. NH-3351-1 WELDED JOINT LOCATIONS
TYPICAL OF CATEGORIES A, B, C, AND D**

NH-3352 Permissible Types of Welded Joints

(a) The permissible types of welded joints and their dimensional requirements are described in the rules for fabrication of Class 1 components for elevated temperature service.

(b) The design of the vessel shall meet the requirements for each category of joint. Butt joints are full penetration joints between plates or other elements that lie approximately in the same plane. Category B angle joints between plates or other elements that have an offset angle, α , not exceeding 30 deg are considered as meeting the requirements for butt joints. Figure NH-3352-1 shows typical butt welds for each category joint.

(c) When Category B joints with opposing lips to form an integral backing strip or joints with backing strips not later removed are used, the suitability for cyclic operation shall be analyzed using a fatigue strength reduction factor of not less than 2 under conditions where creep effects are insignificant [NH-3211(c)]. For conditions where creep effects are significant, see NH-3353(b).

(d) The corners of the end of each nozzle neck extending less than $\sqrt{d_r t_n}$ beyond the inner surface of the part penetrated, shall be rounded to a radius of one-half the thickness, t_r of the nozzle neck, or $\frac{3}{4}$ in. (19 mm), whichever is smaller. The d is the outside diameter of the nozzle.

(e) Where partial penetration welds are used, a fatigue strength reduction factor of not less than 4 shall be used for any related fatigue and analysis under conditions where creep effects are insignificant [NH-3211(c)]. For conditions where creep effects are significant, see NH-3353(b).

(f) Oblique full penetration nozzles are permitted provided (1), (2), and (3) below are satisfied.

(1) The opening shall be completely reinforced, with the reinforcement located in the shell or head of the vessel.

(2) The nozzle shall be subjected to essentially no pipe reactions and no thermal stresses greater than in the vessel itself.

(3) The nozzle wall and the weld shall develop the full strength of the nozzle.

(g) Non-full penetration welds, which are permitted by NH-3354 and NH-3356 at attachment welds, shall have a surface geometry free from weld irregularities and abrupt changes in contour. When the designer determines that contour control is required in order that the criteria of this Subsection be satisfied, the necessary dimensions and tolerances shall be indicated on the fabrication drawings.

(h) Full penetration corner welds [as shown in Figs. NB-4243-1 and NB-4244(b)-1, and defined as Categories C and D vessel welds, or, as similar welds for piping, pumps, and valves] shall be limited to nominal diameters of 4 in. or less.

NH-3353 Design of Welded Construction at Elevated Temperatures

(a) Because of the potential for limited ductility of weld metal at elevated temperatures and the potential for high strain concentrations (both metallurgical and geometric) in the heat affected zones of weldments, the analysis requirements of this paragraph shall be satisfied for the design and location of all pressure

Page 40

retaining and other primary structural welds subjected to metal temperatures where creep effects are significant (NH-3211). The potential for reduced ductility often precludes locating welds in regions of high loading.

FIG. NH-3352-1 TYPICAL BUTT JOINTS

FIG. NH-3352-1 TYPICAL BUTT JOINTS

(b) For meeting the analysis requirements of NH-3251 at elevated temperature weld regions, the assumed weld surface should model the most severe strain concentrations expected in the actual weld placed in service. This geometry may be prescribed on a drawing or may be recorded by prior observation. Prior observations of weld surface geometry can be visual; remote visual (e.g., using a borescope device or making a surface replica); or ultrasonic, based on a weld mockup test in which the same weld procedures are used on the same nominal pipe diameter and wall thickness, or based on a radiographic technique that is suitable for inspection of internal surfaces.

NH-3354 Structural Attachment Welds

(a) Welds for structural attachments shall meet the requirements of NB-4430, NB-4240, and the rules of NH-3352(g).

(b) Those attachments using the exemption of NH-2121(h) shall also comply with the design rules listed below.

(1) The attachment weld shall be located on a rib outside the limits of reinforcement as defined by NB-3334 (see example in Fig. NH-3354-1). The rib may be fabricated by forging, machining, or weld metal build-up.

FIG. NH-3354-1 PERMISSIBLE ATTACHMENT WELD LOCATION

FIG. NH-3354-1 PERMISSIBLE ATTACHMENT WELD LOCATION

(2) The attachment weld shall comply with the rules for Class 1 pressure boundary welds.

Page 41

(3) Loads on the pressure boundary from all permanent attachments shall be considered in the analysis in the Stress Report.

NH-3355 Welding Grooves

The dimensions and shape of the edges to be joined shall be such as to permit complete fusion and complete joint

penetration.

NH-3356 Fillet Welds

NH-3356.1 At Pressure Loaded Joints.

Fillet welds are not permitted for pressure-retaining joints [see NH-3337.3 and NH-3352(g)].

NH-3356.2 At Structural Attachment Joints

(a) Fillet welds conforming to Fig. NB-4427-1 may be used for structural attachments to components, except as restricted and limited by the rules of NB-4433.

(b) Analysis limits for stress limits, strain limits, and damage limits shall be one-half of the allowable values under NH-3200 rules for the weaker of the two base materials being joined.

(c) Evaluation for fatigue shall use a fatigue strength reduction factor of four, and shall include consideration of temperature differences between the component and the attachment and of expansion (or contraction) of the component as a result of internal (or external) pressure.

NH-3357 Thermal Treatment

All pressure vessels and pressure vessel parts shall be given the appropriate postweld heat treatment prescribed in NB-4620.

NH-3360 SPECIAL VESSEL REQUIREMENTS

NH-3361 Category A or B Joints Between Sections of Unequal Thickness

In general, a tapered transition section as shown in Fig. NH-3361-1, which is a type of gross structural discontinuity (NH-3213.2), shall be provided at joints of Categories A and B between sections that differ in thickness by more than one-fourth the thickness of the thinner section. The transition section may be formed by any process that will provide a uniform taper. An ellipsoidal or hemispherical head which has a greater thickness than a cylinder of the same inside diameter may be machined to the outside diameter of the cylinder provided the remaining thickness is at least as great as that required for a shell of the same diameter. The adequacy of the transition shall be evaluated by stress analysis. See NH-3200 for stress intensity limitations and other rules. The requirements of this paragraph do not apply to flange hubs.

GENERAL NOTE: Length of taper may include the width of the weld.

**FIG NH-3361-1 CATEGORY A AND B JOINTS
BETWEEN SECTIONS OF UNEQUAL THICKNESS**

FIG. NH-3361-1 CATEGORY A AND B JOINTS BETWEEN SECTIONS OF UNEQUAL THICKNESS

NH-3362 Bolted Flange Connections

It is recommended that the dimensional requirements of bolted flange connections to external piping conform to ANSI B16.5, Steel Pipe Flanges and Flanged Fittings.

NH-3363 Access Openings

Access openings, where provided, shall preferably consist of handhole or manhole openings having removable covers.

These covers may be located on either the inside or outside of the shell or head openings and may be attached by studs or bolts in combination with gaskets and/or welded membrane seals or strength welds. Plugs using pipe threads are not permitted.

NH-3364 Supports

All vessels shall be so supported and the supporting members shall be arranged and attached to the vessel wall in such a way as to provide for the maximum imposed loadings. The stresses produced in the vessel by such loadings and by steady state and transient

Page 42

thermal conditions shall be subjected to the stress limits of Subsection NH (NCA-3240 and Subsection NF).

NH-3400 DESIGN OF CLASS 1 PUMPS

NH-3410 GENERAL REQUIREMENTS

NH-3410.1 Scope.

The rules of this Subarticle constitute requirements for the design of Class 1 pumps.

(a) The scope of these rules covers the strength and pressure integrity of the structural parts of pumps whose failure would violate the pressure boundary.

(b) Such parts include:

(1) pump casing

(2) pump inlets and outlets

(3) pump cover

(4) clamping ring

(5) seal housings

(6) related bolting

(7) pump internal heat exchanger piping

(8) pump auxiliary nozzle connections up to the face of the first flange or circumferential joint, except as noted below

(9) piping identified with the pump and external to or forming a part of the pressure retaining boundary and supplied with the pump

(10) mounting feet or pedestal supports when integrally attached to the pump pressure retaining boundary and supplied with the pump

(c) The requirements of this Subarticle do not apply to the pump shaft, nonstructural internals, or the seal package. Compliance with the requirements of this Subarticle does not guarantee proper functioning of the component.

NH-3410.2 Definitions

(a) A radially split casing shall be interpreted as one in which the primary sealing joint is radially disposed around the shaft.

(b) An axially split casing shall be interpreted as one in which the primary sealing joint is axially disposed with respect to the shaft.

(c) Seal housing is defined as that portion of the pump cover or casing which forms the primary pressure boundary.

(d) The figures accompanying the pump types are intended to be typical examples to aid in the determination of a pump type and are not to be considered as limiting. Bearing locations and inlet and outlet orientations are optional.

(e) The seal gland plate is to be considered a part of the seal housing and therefore is subject to Code requirements. The seal chamber pressure shall be specified in the Design Specification.

**FIG. NH-3410.2-1 TYPICAL SINGLE VOLUTE
CASING**

FIG. NH-3410.2-1 TYPICAL SINGLE VOLUTE CASING

FIG. NH-3410.2-2 TYPICAL DOUBLE VOLUTE CASING

FIG. NH-3410.2-2 TYPICAL DOUBLE VOLUTE CASING

(f) Figures NH-3410.2-1 and NH-3410.2-2 show typical single and double volute casings, respectively.

NH-3411 Acceptability of Large Pumps

(a) The requirements for the design of a Class 1 pump having an inlet connection greater than 4 in. nominal pipe size diameter are stated in NH-3411.1.

(b) In cases of conflict between this Subarticle and the rules of Subarticles NH-3100 and NH-3200, the requirements of NH-3400 shall govern.

NH-3412 Acceptability of Small Pumps

(a) The requirements for the design of a Class 1 pump having an inlet connection 4 in. nominal pipe size diameter or smaller are stated in NH-3111.1.

(b) In cases of conflict between this Subarticle and the rules of Subarticles NH-3100 and NH-3200, the requirements of NH-3400 shall govern.

NH-3413 Alternative Design Rules

For any size Class 1 pump, an experimental stress analysis may be used to determine elastic stresses and strains used with NH-3200 limits and/or Appendix T limits provided (a) and (b) below are satisfied.

(a) The experimental stress analysis is in accordance with the procedures of Section III, Appendix II.

(b) The NH-3421 design requirements are met.

NH-3420 DESIGN CONSIDERATIONS

NH-3421 Design Requirements

NH-3421.1 Loadings.

Loadings, design and service conditions, special considerations, and general design rules are described in Subarticle NH-3100.

NH-3421.2 Piping Under External Pressure.

Piping located within the pressure retaining boundary of the pump shall be designed in accordance with NH-3250.

NH-3421.3 Piping Under Internal Pressure.

Piping identified with the pump and external to or forming a part of the pressure retaining boundary, such as auxiliary water connections, shall be designed in accordance with NH-3600.

NH-3421.4 Piping Connections Using Partial Penetration Welds.

Partial penetration welds are permitted for piping connections 2 in. and under in nominal pipe diameter (DN 50) when used in accordance with the rules of NH-3337.3 and NH-3352.

NH-3421.5 Bolting - Radially Split Configurations.

Bolting in axisymmetric arrangements involving the pressure boundary shall be designed in accordance with the procedure described in NH-3230.

NH-3421.7 Supports.

Pump supports shall be designed in accordance with the requirements of Subsection NF if negligible creep effects are present during the cycle. Otherwise, the supports shall comply with NH-3200.

NH-3421.8 Axially Oriented Inlets and Outlets

(a) An axially oriented pump casing inlet or outlet shall be considered an opening in a vessel and will require reinforcement. It shall be treated as required in NH-3331 through NH-3336.

(b) To avoid stress concentrations, the outside radius r_2 Fig. NB-3441.3-2, shall not be less than one-half the thickness of the inlets and outlets as reinforced.

NH-3421.9 Radially Oriented Inlets and Outlets.

Reinforcement of radially oriented inlets and outlets is required. NH-3330 and NH-3421.11 shall apply.

NH-3421.10 Tangential Inlets and Outlets.

Reinforcement of tangential inlets and outlets is required. NH-3330 and NH-3421.11 shall apply.

NH-3421.11 Stress Analysis, Nozzle Loads, and Reinforcement

(a) *Stress Analysis.* The analysis methods in NB-3400 shall apply only to elastic analysis. In particular, stress equations may be used in satisfying the limits on load controlled stresses, and they may be applied to analysis under NH-3250 when creep effects are insignificant [NH-3211(c)].

(b) *Nozzle Loads.* The forces and moments produced by the connected piping on the pump inlet and outlet shall be furnished to the pump supplier by the user in accordance with NCA-3254.

(c) *Reinforcement.* The distance.. in Fig. NH-3421.11-1 is the limit of reinforcement. The value of.. shall be determined from the relationship:

$$.. = 0.5 \sqrt{r_m t_m} \text{ in., where}$$
$$r_m = r_i + 0.5 t_m \text{ in.}$$

r_i	= inlet or outlet inside radius, = $d_i/2$, in.
t_m	= mean inlet or outlet wall thickness, in., taken between section x-x and a parallel section y-y tangent to crotch radius

NH-3421.12 Earthquake Design Analysis.

When earthquake loadings are specified in the Design Specification (NCA-3250), the designer shall assess the ability of the pump to withstand such loadings while maintaining the integrity of the pressure retaining materials. For example, the assessment should include inertia effects from moving parts and piping reactions.

NH-3421.13 Attachments.

Attachments are permitted when designed in accordance with NH-3135 and NB-4430.

**FIG. NH-3421.11-1 MINIMUM TANGENTIAL
INLET AND OUTLET WALL THICKNESS**

FIG. NH-3421.11-1 MINIMUM TANGENTIAL INLET AND OUTLET WALL THICKNESS

NH-3421.14 Appurtenances.

Appurtenances as defined in NCA-1260 are permitted provided the requirements for documentation are fulfilled as described in NCA-1231.

NH-3421.15 Pump Covers.

Pump covers shall be designed in accordance with NH-3200.

NH-3421.17 Cladding.

The design of clad pressure retaining parts shall be in accordance with NH-3227.8.

NH-3421.19 Cutwater Tip Stresses.

It is recognized that localized high stresses can occur at the cutwater tip of volute casings (Fig. NB-3441.3-2). Adequacy of the design in this area shall be demonstrated as follows:

(a) an evaluation of load controlled stresses showing that sufficient area is available in the volute casing to meet the stress limit of NH-3220; and

(b) an evaluation of the localized stress at the cutwater tip by:

(1) an investigation through experimental analysis in accordance with Section III, Appendix II; or by

(2) a detailed stress analysis; or by

(3) a combination of the above.

(c) Where experimental and/or detailed stress analysis is used, stress and strain intensity at this point shall meet the requirements of NH-3250.

NH-3430 PUMP TYPES

Design requirements for specific pump types are listed in NB-3430.

NH-3500 DESIGN OF CLASS 1 VALVES

NH-3510 DESIGN REQUIREMENTS

NH-3511 Acceptability

(a) The requirements for acceptability of a Class 1 valve design are stated in NH-3111.1.

(b) Compliance with the requirements of this Subarticle does not guarantee proper functioning of the component.

(c) In cases of conflict between this Subarticle and the rules of Subarticles NH-3100 and NH-3200, the requirements of NH-3500 shall govern.

NH-3512 Stress Analysis

The analysis methods in NB-3500 shall apply only to elastic analysis. In particular, the stress indices and stress equations may be used in satisfying the limits on load controlled stresses, or they may be applied to analyses under NH-3250 when creep effects are insignificant [NH-3211(c)].

NH-3524 Earthquake Design Analysis

(a) When earthquake loadings are specified in the Design Specifications (NCA-3250), the designer shall assess the ability of the valve to withstand such loadings while maintaining the integrity of the pressure boundary materials. For example, the assessment should include inertia effects from moving parts and piping reactions.

(b) Where valves are provided with operators having extended structures and the Design Specifications state that these structures are essential to maintaining pressure integrity, an analysis may be based on static forces resulting from equivalent earthquake accelerations acting at the centers of gravity of the extended masses.

NH-3526 Level C Service Limits

(a)

used in evaluating these conditions shall be those of NH-3510.

(b) If valve function must be assured during Level C Service Loadings, this requirement shall be included in the Design Specifications and the specified emergency

Page 45

conditions for the plant shall be considered as the Level A Service Loadings for the valve.

NH-3544 Body Shape Rules

The rules of NB-3544 provide a convenient guide for design of valve bodies for elevated temperature service. However, specific rules may be bypassed when justified by analysis.

NH-3546 Other Valve Parts

(a) For valve stems, stem retaining structures, and other significantly stressed valve parts whose failure can lead to gross violation of the pressure retaining boundary, the primary stresses shall not exceed the stress intensity limit, S_o . For materials not covered in Tables I-14.1 but allowed under the rules of NB-2121(c), the S_o values are those given in Tables 2A and 2B of Section II, Part D, Subpart 1.

(b) Valve designs requiring solenoid plunger type or electromagnetic indicator type core tubes may substitute NH-3600 rules to govern the requirements for the extension.

NH-3550 CYCLIC LOADING REQUIREMENTS

When cyclic conditions exist, the rules for analysis are covered by NH-3250 and NH-3512.

NH-3600 PIPING DESIGN

NH-3610 GENERAL REQUIREMENTS

NH-3611 Acceptability

(a) The requirements for acceptability of a Class 1 piping system design are stated in NH-3111.1.

(b) In cases of conflict between this Subarticle and the rules of Subarticles NH-3100 and NH-3200, the requirements of NH-3600 shall govern.

(c) The designer is cautioned to note that dimensional standards for pipe fittings control the minimum wall thickness, but do not establish maximum wall or contour. These additional dimensional controls may have to be imposed by the designer when significant thermal transients must be considered.

NH-3612 Pressure-Temperature Ratings for Piping Components

(a) Where piping systems operating at different pressures are connected by a valve, the valve shall be designed for the higher pressure system requirements of pressure and temperature. The lower pressure system may be designed to the higher pressure system requirements. If the lower pressure system is not designed to the higher pressure system requirements, pressure relief devices or safety valves shall be provided to protect the lower pressure system. The pressure relief devices or safety valves shall adjoin or be as close as possible to the interconnecting valve. All valves, devices, and piping related to pressure relief functions shall meet requirements for overpressure protection of systems operating at elevated temperatures.

(b) Where pressure reducing valves are used and one or more pressure relief devices or safety valves are provided, bypass valves may be provided around the pressure reducing valves. The combined relieving capacity requirements and operational requirements shall be given by the rules on overpressure protection.

(c) Drip lines from steam headers, mains, separators, or other equipment operating at different pressures shall not discharge through the same trap. Where several traps discharge into a single header that is or may be under pressure, a stop valve and a check valve shall be provided in the discharge line from each trap. The design pressure of trap discharge

piping shall not be less than the maximum discharge pressure to which it may be subjected. Trap discharge piping shall be designed for the same pressure as the trap inlet piping unless the discharge piping is vented to a system operated under lower pressure and has no intervening stop valves.

(d) Pump discharge piping shall be designed to withstand the maximum pressure exerted by the pump at any load, including that with a closed discharge valve, and for the highest coincident metal temperature.

(e) Where a fluid passes through heat exchangers in series, the design temperature of the piping in each section of the system shall conform to the most severe temperature condition expected to be produced by heat exchangers in that section of the system.

NH-3620 DESIGN CONSIDERATIONS

NH-3622 Dynamic Effects

NH-3622.1 Impact.

Impact forces caused by either external or internal conditions shall be considered in the piping design.

Page 46

NH-3622.2 Earthquake.

The effects of earthquake shall be considered in the design of piping supports and restraints. The loadings, movements (earthquake anchor movements), and number of cycles to be used in the analysis shall be part of the Design Specifications (NCA-3250). The stresses resulting from these earthquake effects must be included with weight, pressure, or other applied loads when making the required analysis.

NH-3622.3 Vibration.

Piping shall be arranged and supported so that vibration will be minimized. The designer shall be responsible, by design and by observation under startup or initial operating conditions, for ensuring that vibration of piping systems is within acceptable levels.

NH-3623 Weight Effects

Piping systems shall be supported to provide for the dynamic effects of any contained fluid and for the fixed weights of piping, insulation, and other imposed mechanical loads in the piping.

NH-3624 Loadings, Displacements, and Restraints

The design of piping systems shall take into account the forces and moments resulting from thermal expansion and contraction, equipment displacements and rotations, and the restraining effects of hangers, supports, and other localized loadings.

NH-3626 Special Drainage Problems

(a) For piping systems which must be drained, consideration shall be given to creep induced sag which may develop between pipe supports in elevated temperature systems.

(b) For piping systems which drain at intermediate or elevated temperatures, consideration shall be given to load cycles associated with this condition.

NH-3627 Considerations for Liquid Metal Piping

NH-3627.1 Location.

Routing of liquid metal piping in the vicinity of steam and water piping shall be avoided.

NH-3627.2 Heat Tracing.

Liquid metal piping shall be provided with heat tracing which shall be capable at least of maintaining the liquid metal in a molten condition. The use of steam or water for heat tracing shall not be permitted. Control of heat tracing shall provide for melting solidified liquid metal progressively from a free surface so that overpressure protection for the expansion of melting will not be required. Control shall also be adequate to assure that design rate of temperature change and temperature limits will not be exceeded.

NH-3627.3 Filling and Draining

(a) Liquid metal fill and drain shall be accommodated by means of an inert cover-gas purge and vent system. Volumetric expansion of liquid metal shall be provided for by a free liquid surface and a vented cover-gas space.

(b) All liquid metal piping shall be sloped to permit complete drainage by gravity into drain reservoirs. The use of small auxiliary drain lines shall be avoided.

NH-3640 PRESSURE DESIGN OF COMPONENTS

NH-3641.1 Straight Pipe.

The minimum wall thickness of pipe shall not be less than t_m , where t_m is determined from the requirements for Design Loadings analysis in NH-3222.1.

NH-3642 Curved Segments of Pipe

NH-3642.1 Pipe Bends.

The design of pipe bends shall provide that the completed bend will satisfy the analysis requirements of NH-3200. In addition to the basic dimensions of the bend (i.e., pipe diameter, wall thickness, and bend radius), the designer shall consider the secondary deformations and irregularities inherent to the bending process and shall define tolerances as needed to ensure conformance of the finished piping with the rules for analysis. In particular, the considerations of (a) through (e) below shall be taken into account.

(a) *Wall thickness* after bending shall not be less than the minimum wall thickness required for straight pipe.

(b) *Wall thinning and thickening.* Experience has shown that with good shop practices the relationship of the finished bend thickness to that of the straight pipe from which it is bent will be in accordance with Table NH-3642.1-1.

(c) *Ovality*

(d) *Wrinkling*, defined as the difference between the average outside diameter of any two adjacent wrinkles and the outside diameter of the enclosed valley, shall normally be held to 3%.

(e) *Surface irregularities*

**TABLE NH-3642.1-1
BEND RADIUS VS THICKNESS**

Radius of Bends	Minimum Thickness Recommended Prior to Bending [Note (1)]
6 pipe diameters or greater	1.06 t_m
5 pipe diameters	1.08 t_m
4 pipe diameters	1.16 t_m
3 pipe diameters	1.25 t_m

NOTE:

(1) t_m is the required minimum thickness of the finished bend.

TABLE NH-3642.1-1 BEND RADIUS VS THICKNESS

NH-3643 Intersections

The rules of NH-3643 may be satisfied by demonstrating, by analysis or experiment or both, that the component fully complies with the requirements of NH-3200.

NH-3643.1 General Requirements

(a) Openings shall be circular, elliptical, or of any other shape that results from the intersection of a circular or elliptical cylinder with a cylindrical shape.

(b) All references to dimensions in this and succeeding paragraphs apply to the finished dimensions, excluding material added for corrosion allowance.

(c) Any type of opening permitted in these rules may be located in a welded joint.

(d) The requirements of NB-3643.3 shall be met for the branch connections listed in NH-3642.1(b), (c) and (d), except that S_o and NH-3641.1 should be used instead of callouts (NB-3643.3) to S_m and NB-3641.1, respectively.

NH-3643.2 Branch Connections.

Branch connections in piping may be made by using one of the products or methods set forth in (a), (b), and (c) below.

(a) flanged, butt weld, or socket weld in accordance with the applicable ANSI standards listed in Table NB-3132-1, subject to the limitations or requirements stated elsewhere in this Subsection [for example, see NH-3660(b)];

(b) contour outlet fittings having integral reinforcement and attached by butt welding, or flanged ends for attachment to the branch pipe. These are limited to types that have integral reinforcement and are attached to the main run by welding, as illustrated in figures contained in the rules of NH-4000;

(c) an extruded outlet at right angles to the run pipe;

(d) For conditions where creep effects are insignificant [NH-3211(c)], intersecting pipes may be joined by welding the branch pipe to the run pipe as shown in Fig. NB-3643.3(a)-2. For such intersections, the intersection angle shall not be less than 60 nor greater than 120 deg.

NH-3644 Miters

Mitered joints may be used for elevated temperature service subject to meeting analysis requirements of NH-3200 and also complying with the requirements for fabrication. Maximum angles shall be $22\frac{1}{2}$ deg. or less.

NH-3645 Attachments

The rules of NH-3135 apply.

NH-3646 Closures

(a) Closures in piping systems may be made by use of closure fittings, such as blind flanges or welded plugs or caps.

(b) The use of such closures in elevated temperature service shall be subject to meeting the analysis requirements of NH-3200.

(c) For closures not subjected to elevated temperatures, the rules of NB-3646 shall apply.

NH-3647 Flanged Joints

(a) The use of flanged joints should be minimized.

(b) Any flanged joint shall be located where regular maintenance can be performed.

(c) Flanged joints exposed to elevated temperature service shall comply with the analysis requirements of NH-3200.

(d) Flanged joints not exposed to elevated temperatures shall meet the requirements of NB-3647.

NH-3648 Reducers

Reduced fittings shall be considered suitable for use subject to complying with the analysis requirements of NH-3200.

NH-3649 Pressure Design of Other Pressure Retaining Components

Other pressure retaining components manufactured in accordance with the standards listed in Table NB-3132-1 shall be considered suitable for use provided the design is consistent with the design philosophy embodied in Subsection NH. Pressure retaining components not included in Table NB-3132-1 may be used if they satisfy the requirements of NH-3200. The pressure

Page 48

design shall be based on an analysis consistent with the general design philosophy embodied in Subsection NH, or experimental stress analysis in accordance with NH-3649.1 below.

NH-3649.1 Experimental Analysis

(a) An experimental analysis, if used, shall adhere to the methods and principles in Appendix II, with changes appropriate for elevated temperature conditions.

(b) As part of the experimental analysis, an ANSI B16.9-type burst test shall be performed on the component. The

bursting pressure shall equal or exceed that of the weakest pipe to be attached to the component, where the pipe burst pressure is calculated by the equation:

$$P = 2 St/D_o$$

where

D_o	= outside diameter of pipe, in.
S	= specified minimum tensile strength of pipe material, psi
t	= minimum specified wall thickness of pipe, in.

NH-3650 ANALYSIS OF PIPING COMPONENTS

NH-3651 General Requirements

Until special rules for piping components are developed for elevated temperature service, the analysis requirements are given by (a) and (b) below.

(a) The structural analysis shall demonstrate (by analysis or experiment or both) that the component fully complies with the requirements of NH-3200.

(b) The stress indices and stress equations of NB-3600 may be used to define stress intensities whenever linearly elastic material models are appropriate, for example, in satisfying the limits on load controlled stresses (NH-3220), or in satisfying strain and deformation limits using elastic and simplified inelastic analyses (T-1320, T-1330, and T-1430).

NH-3660 DESIGN OF WELDS

(a) Weld designs shall comply with the requirements of NH-3350 and NH-3337.

(b) Socket welds and seal welded threads are generally not permitted for joints exposed to elevated temperature service. Exceptions shall be allowed only if the analysis requirements of this Subsection are satisfied at each junction and only if each application is specifically described as part of the Design Specifications (NCA-3250). In almost all systems containing nuclear coolant, such crevices and cracks are undesirable due to potential for trapped radioactive particles, problems with cleaning fluids, and impurities in the coolant. Joints allowed under the rules of this paragraph shall be limited to nominal diameters of 1 in. (25 mm) and smaller.

(c) Full penetration corner welds may be used (in addition to butt welds) for attaching branch connections and closures to piping in accordance with NH-3643.2 and NH-3646, respectively.

NH-3670 SPECIAL PIPING REQUIREMENTS

NH-3671 Nonwelded Piping Joints

NH-3671.1 Excluded Designs

(a) Flared, flareless, and compression-type tubing fittings shall not be used.

(b) Expanded joints shall not be used.

(c) Caulked or leaded joints shall not be used.

(d) Soldered joints shall not be used.

NH-3671.6 Brazed Joints.

The rules of NB-3671.6 apply. Any cooling liquid (or gas), including liquid sodium, is acceptable in the proximity of such joints provided the selected brazing material is compatible with the liquid.

NH-3671.7 Patented Joints.

Mechanical joints, for which no standards exist, and other patented joints may be used provided that:

- (a) Provision is made to prevent separation of the joints under all conditions of service;
- (b) They are accessible for maintenance, removal, and replacement after operation;

(c) A prototype joint has been subjected either to performance tests to determine the safety of the joint under simulated service conditions (including the service fluid), or the joint meets all analysis requirements of NH-3200. When vibration, fatigue, cyclic conditions, low temperature, thermal expansion, or hydraulic shock is anticipated, the applicable conditions shall be incorporated in the tests or analyses. The mechanical joints shall be sufficiently leak tight to satisfy the requirements of the Design Specifications (NCA-3250).

NH-3672 Expansion and Flexibility

(a) In addition to meeting the design requirements for pressure, weight, and other loadings, piping systems shall be designed to absorb or resist thermal expansion or contraction or similar movements imposed by other sources, and shall meet the criteria as specified in NH-3200.

Page 49

Piping systems shall be designed to have sufficient flexibility to prevent the movements from causing:

- (1) failure of piping or anchors from overstress or overstrain;
- (2) leakage at joints;
- (3) detrimental distortion of connected equipment resulting from excessive thrusts and moments.

(b) In this Subsection, the effects of stresses, caused by pressure, thermal expansion and other loads, and their stress intensification factors, are considered cumulatively.

(c) When calculating the flexibility of a piping system between anchor points, the system between the anchor points shall be treated as a whole. The significance of all parts of the line and of all restraints, such as supports or guides, including intermediate restraints introduced for the purpose of reducing moments and forces on equipment or small branch lines, shall be considered.

(d) Comprehensive calculations shall take into account the flexibility factors found to exist in components other than straight pipe. Credit may be taken where extra flexibility exists in such components.

(e) Calculations shall consider line expansion as well as linear and angular movements of the equipment and supports attached to the piping.

(f) Where assumptions are used in calculations or model tests, the likelihood of attendant underestimates of forces, moments, and stresses, including the effects of stress intensification, shall be evaluated.

(g) Cold springing may provide a beneficial effect in assisting a system to attain its most favorable position sooner and with the least initial inelastic straining. The effect of cold springing shall be analyzed as any other movement in the system is analyzed. The maximum stress allowed due to cold springing is $2.0 S_m$ at the cold spring temperature. Since the usual erection procedures may not permit accurate determination of cold spring in a piping system, the allowable reduction of forces and moments at anchors or equipment caused by cold springing shall be limited to no more than two-thirds of the calculated reduction. At elevated temperatures, creep and creep relaxation shall be considered in the analysis of the cold sprung piping and in establishing the steady state configuration of the piping system.

NH-3674 Design of Piping Supports

Pipe supports shall be designed in accordance with applicable rules of Subsection NF except for the stress analysis, which shall be in accordance with the rules of NH-3200.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NH-4000

ARTICLE NH-4000 FABRICATION AND INSTALLATION

Page 51

NH-4100 GENERAL REQUIREMENTS

NH-4110 INTRODUCTION

(a) Those portions of the component which do not experience elevated temperature service (as defined by the rules of NH-3000) may use the NB-4000 rules as applicable.

(b) Those portions of the component that do not meet the conditions in (a) above shall comply with the provisions of this Subsection in addition to the rules of NB-4000.

(c) Those portions of the component on which options (a) or (b) above apply shall be identified during all phases of manufacture and installation.

NH-4212 Effects of Forming and Bending Processes

The rules of this paragraph shall supplement those of NB-4212 and NB-4213. Any process may be used to form or bend pressure retaining materials, including weld metal, provided that the requirements of the subparagraphs below are met.

(a) Post fabrication heat treatment [in accordance with (b) below] of materials which have been formed during fabrication, shall be required unless one of the following conditions are met.

(1) Maximum fabrication induced local strains¹ do not exceed 5%,² regardless of the service temperature.

(2) Written technical justification shall be provided in the Design Report for not performing heat treatment, subsequent to straining, or for the use of an alternate heat treatment procedure, to that specified in (b) below, for fabrication induced strains greater than 5%.

1 Strain is defined as the maximum local fiber elongation or contraction per unit length; and where more than one strain increment occurs (e.g., biaxiality or reversed bending), it shall be the sum of the absolute values of all the strain increments.

2 Strain resulting from final straightening operations performed on materials furnished in the solution annealed or heat treated condition need not be included in the computation of strain.

The justification should provide assurance that the resultant material property capabilities are adequate for the intended service (fatigue, creep rupture, impact toughness, etc.) and shall include consideration of property variability through the material section. This option is not permitted for certain materials if the components are subjected during Levels A, B, and C service, or for design conditions when only design conditions are specified, to short-time high temperature excursions that result in accumulated temperature exposures exceeding the maximum permissible values shown in Fig. NH-4212-1. This option is also not permitted for any austenitic material that is subjected to greater than 20% strain.¹

(3) The roll threaded portion of bolting material is exempt from the heat treatment requirement.

(b) When required, the post fabrication heat treatment shall be in accordance with the following:

(1) For ferritic materials, the post fabrication heat treatment shall consist of heating to temperatures listed in Table NB-4622.1-1 for the appropriate alloy P-Number. Holding times shall also be in accordance with this Table based on the material thickness at the point of maximum strain. This heat treatment shall be included in material certification per NB-2211, the forming qualifications as required by NB-4213, and applicable weld procedure qualifications.

Alternatively, the base material and welds may be reheat treated and recertified in accordance with the applicable material specification and requirements in NB-2400. Reheat treatment may entail appropriate cooling from hot working temperatures above the upper critical temperature of the respective material provided required material property levels are recertified.

(2) For austenitic materials, the post fabrication heat treatment shall consist of the heat treatment specified in the base material specification except that Ni-Fe-Cr Alloy 800H shall be heat treated at 2,050°F (1121°C) minimum.

Following reheat treatment, the final grain size of Alloy 800H shall be verified as being not finer than

Page 54

ASTM 5. If reheat treatment is employed, the designer shall be alerted to the possibility for material yield strength reductions, and the effect on buckling analysis must be accommodated as dictated by design rules.

FIG. NH-4212-1 PERMISSIBLE TIME/TEMPERATURE CONDITIONS FOR MATERIAL WHICH HAS BEEN COLD WORKED >5% AND <20% AND SUBJECTED TO SHORT-TIME HIGH TEMPERATURE TRANSIENTS. THE SUM OF TIME AT EVERY TEMPERATURE SHALL DETERMINE A POINT WITHIN THE DESIGN REGION OF THE FIGURE FOR THE SPECIFIC MATERIAL. FOR MULTIPLE TEMPERATURE/TIME COMBINATIONS, THE LINEAR SUMMATION OF LIFE FRACTION SHALL NOT EXCEED 1.0, THE MATERIAL LIMIT

FIG. NH-4212-1 PERMISSIBLE TIME/TEMPERATURE CONDITIONS FOR MATERIAL WHICH HAS BEEN COLD WORKED >5% AND <20% AND SUBJECTED TO SHORT-TIME HIGH TEMPERATURE TRANSIENTS. THE SUM OF TIME AT EVERY TEMPERATURE SHALL DETERMINE A POINT WITHIN THE DESIGN REGION OF THE FIGURE FOR THE SPECIFIC MATERIAL. FOR MULTIPLE TEMPERATURE/TIME COMBINATIONS, THE LINEAR SUMMATION OF LIFE FRACTION SHALL NOT EXCEED 1.0, THE MATERIAL LIMIT

NH-4240 SPECIAL JOINTS AND FITTINGS - ADDED RULES FOR NB-4240

The rules of NH-3000 generally discourage the use of socket weld fittings and seal welded threads. If used, the designer shall evaluate whether assembly of socket welds should allow for an axial gap after welding which will allow free thermal

growth of the male coupling within the socket without bottoming out during the intended service. If a gap is deemed necessary, it shall be verified either by radiographic examination or by following special written procedures (see the rules of NH-3000).

NH-4424 Surfaces of Welds

As-welded surfaces are permitted provided that the surface geometry is considered in the stress analysis in accordance with the rules for design of Class 1 elevated temperature components.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NH-5000

ARTICLE NH-5000 EXAMINATION

Page 57

Page 59

NH-5100 GENERAL REQUIREMENTS FOR EXAMINATION

NH-5110 GENERAL REQUIREMENTS

(a) Those portions of the component designated (in accordance with the rules of NH-3000) as not to experience elevated temperature service may use the NB-5000 rules unchanged by rules in later paragraphs of this Subsection.

(b) Those portions of the component that do not meet the conditions in (a) above shall comply with the provisions of this Subsection in addition to the rules of NB-5000.

(c) Those portions of the component which use option (a) above shall be identified during all steps of examination.

NH-5130 EXAMINATION OF WELD EDGE PREPARATION SURFACES

The rules of this paragraph shall be substituted for the first sentence of NB-5130.

All weld edge preparation surfaces for vessel weld joint Categories A, B, C, and D and similar pressure boundary welds in other components shall be examined by either the magnetic particle or liquid penetrant method. This requirement shall not apply to welds where the nominal thickness is 1 in. (25 mm) or less.

NH-5200 REQUIRED EXAMINATION OF WELDS

NH-5210 CATEGORY A VESSEL WELDED JOINTS AND LONGITUDINAL WELDED JOINTS IN OTHER COMPONENTS

The rules of this paragraph shall be substituted for those of NB-5210.

All longitudinal butt welds of Category A, as defined in NB-3351.1, and all similar pressure boundary welds in other Class 1 components shall be examined in accordance with the requirements of (a) and (b) below.

(a) External weld surfaces, accessible internal weld surfaces, and adjacent base material for at least $\frac{1}{2}$ in. (13 mm) outside the edges of the completed weld shall be examined by either the magnetic particle or liquid penetrant method.

(b) All weld metal and adjacent base material for at least $\frac{1}{2}$ in. (13 mm) outside the edges of each weld shall be volumetrically examined by an appropriate method from the three listed below:

(1) radiography plus ultrasonic examination, where the radiography may be performed prior to any intermediate or required postweld heat treatment, provided the ultrasonic examination is performed after the final postweld heat treatment;

(2) radiography plus eddy current examination, provided the portion of the weld being examined is less than $\frac{1}{4}$ in. (6 mm)

thick;

(3) radiography at two different angles - one angle within 15 deg. of perpendicular to the surface, the other at some angle appropriate for revealing any lack of fusion and cracking defects at the weld metal/base material interface near the root pass.

NH-5220 CATEGORY B VESSEL WELDED JOINTS AND CIRCUMFERENTIAL WELDED JOINTS IN OTHER COMPONENTS

The rules of this paragraph shall be substituted for those of NB-5220.

(a) For component regions with nominal diameter greater than 4 in., all circumferential butt welds similar to Category B, as defined in NB-3351.2, shall be examined in accordance with the requirements of NH-5210.

Page 60

(b) For component regions with nominal diameter of 2 in. or less, all circumferential butt welds similar to Category B, along with adjacent base material for at least $\frac{1}{8}$ in. (3.2 mm) outside the edges of the completed weld, shall be radiographed. For component regions with a nominal diameter over 2 in. (51 mm) but not exceeding 4 in. (102 mm), circumferential butt welds similar to Category B welds shall be radiographed. The adjacent base material for a distance outside the edges of the completed weld equal to the greater of $\frac{1}{8}$ in. (3.2 mm) or t , but not to exceed $\frac{1}{2}$ in. (13 mm) where t is the thickness of the weld, shall also be radiographed. In addition, each completed weld shall undergo surface examination in accordance with the requirements of NH-5210(a).

NH-5230 CATEGORY C VESSEL WELDED JOINTS AND SIMILAR WELDED JOINTS IN OTHER COMPONENTS

The rules of this paragraph shall be substituted for those of NB-5230.

(a) For component regions with nominal diameter greater than 4 in. (102 mm), all full penetration welds similar to Category C, as defined in NB-3351.3, shall be examined in accordance with the requirements of NH-5210.

(b) For component regions with nominal diameter of 4 in. (102 mm) or less, all full penetration welds similar to Category C, along with adjacent base material for at least $\frac{1}{2}$ in. (13 mm) outside the edges of the completed weld, shall be radiographed. In addition, each completed weld shall undergo surface examination in accordance with the requirements of NH-5210(a). For full penetration corner welds, the requirements of (c) and (d) below shall replace the requirements of this paragraph.

(c) For component regions with nominal diameter of 4 in. (102 mm) or less, all full penetration corner welds similar to sketches (a), (b), and (c) of Fig. NB-4243-1 shall be radiographed; this radiography may require special techniques such as the use of multiple exposures. In addition, each completed weld shall undergo surface examination in accordance with the requirements of NH-5210(a).

(d) For component regions with nominal diameter of 4 in. (102 mm) or less, all full penetration corner welds similar to sketches (d), (e), and (f) of Fig. NB-4243-1 shall be examined in accordance with the requirements of (c) above. In addition, the fusion zone and the parent metal beneath the attachment surface shall be ultrasonically examined after welding to reveal any lack of fusion and laminar defects.

NH-5240 CATEGORY D VESSEL WELDED JOINTS AND BRANCH AND PIPING CONNECTIONS IN OTHER COMPONENTS

The rules of this paragraph shall be substituted for those of NB-5240. All welded joints of Category D, as defined in NB-3351.4, and similar pressure boundary welds in other components shall be examined in accordance with the requirements listed below.

NH-5242 Butt Welded Nozzles and Branch and Piping Connections

(a) Butt welded attachment welds for nozzles and branch connections with nominal diameter greater than 4 in. (102 mm) shall be examined in accordance with the requirements of NH-5210. These welds shall be full penetration butt welds

through either the component wall or the nozzle wall, as shown in Fig. NB-4244(a)-1.

(b) Butt welded attachment welds for nozzles and branch connections with nominal diameter of 4 in. (102 mm) or less shall be examined by radiography. The examination shall cover the weld metal and the adjacent base material for at least $\frac{1}{2}$ in. (13 mm) outside the edges of the completed weld. In addition, each completed weld shall undergo surface examination in accordance with the requirements of NH-5210(a).

NH-5243 Full Penetration Corner Welded Nozzles and Branch and Piping Connections

(a) Full penetration corner welded attachment welds for nozzles and branch connections with nominal diameter greater than 4 in. (102 mm) shall be examined in accordance with the requirements of NH-5210.

(b) For nozzles and branch connections with nominal diameter of 4 in. (102 mm) or less, all full penetration corner welded attachment welds similar to sketch (f) of Fig. NB-4244(b)-1 shall be radiographed; this radiography may require special techniques such as the use of multiple exposures. The examination shall cover the weld metal and the adjacent base material for at least $\frac{1}{2}$ in. (13 mm) outside the edges of the completed weld. In addition, each completed weld shall undergo surface examination in accordance with the requirements of NH-5210(a).

Page 61

(c) For nozzles and branch connections with nominal diameter of 4 in. (102 mm) or less, all full penetration corner welded attachment welds similar to sketches (a), (b), (c), (d), (e), and (g) of Fig. NB-4244(b)-1 shall be examined in accordance with the requirements of (b) above. In addition, the fusion zone and the parent material beneath the attachment surface shall be ultrasonically examined after welding to reveal any lack of fusion and laminar defects.

NH-5244 Deposited Weld Metal as Reinforcement for Openings and Attachment of Nozzles, Branch, and Piping Connections

(a) Weld buildup deposits may be made to a surface as shown in Step 1 of Fig. NB-4244(c)-1 for nozzle and branch connections. When such weld deposits are made, the fusion zone and the parent metal beneath the weld shall be ultrasonically examined after welding to reveal any lack of fusion and laminar defects. Nozzles may then be attached as shown in Step 2 of Fig. NB-4244(c)-1.

(b) Full penetration attachment welds, similar to those shown in Fig. NB-4244(c)-1, shall be radiographed; this radiography may require special techniques such as the use of multiple exposures. The examination shall cover the weld metal and the adjacent base material for at least $\frac{1}{2}$ in. (13 mm) outside the edges of the completed weld. In addition, each completed weld shall undergo surface examination in accordance with the requirements of NH-5210(a).

NH-5245 Partial Penetration Welds

Partial penetration welds shall be used only for the small diameter applications allowed by the rules of NH-3000. Partial penetration welds as shown in Figs. NB-4244(d)-1 and NB-4244(d)-2 shall be examined progressively using either the magnetic particle or the liquid penetrant method. The increments of examination shall be the lesser of one-half of the maximum weld dimension measured parallel to the center line of the connections, or $\frac{1}{2}$ in. (13 mm). In addition, each completed weld shall undergo surface examination in accordance with the requirements of NH-5210(a).

NH-5246 Full Penetration Category D Welds at Oblique Connections

(a) Full penetration welds shall be examined in accordance with the requirements of NH-5210. Prior to examination, backing rings shall be removed and the nozzle bore surface finish shall be suitable for the type of examination.

(b) The radiographic examination in (a) above is not required provided all the conditions listed below are met.

(1) The weld is made as per Fig. NB-4244(e)-1, Step 1. After attachment [Step 1, sketch (a)] or after cladding [Step 1, sketch (b) or (c)], the weld, weld fusion zone, and base metal under the attachment shall have been ultrasonically examined.

(2) The weld is made as per Fig. NB-4244(e)-1, Step 2, and the magnetic particle or liquid penetrant method shall have been used to progressively examine the weld at the lesser of one-half the thickness of the weld joint, or each $\frac{1}{2}$ in. (13 mm) of weld thickness.

(3) A surface examination using the magnetic particle or liquid penetrant method shall have been made on the root pass weld.

(4) The angle which the nozzle axis makes with the component wall at the point of attachment is not smaller than 40 deg.

NH-5260 FILLET, SOCKET, AND ATTACHMENT WELDS

NH-5261 Fillet and Socket Welds

The rules of this paragraph shall be substituted for NB-5260. Fillet and socket welds shall be used only for the small diameter applications allowed by the rules of NH-3000. Completed surfaces of fillet and socket welds shall be examined visually and by either the magnetic particle or liquid penetrant methods. To ensure that proper fit-up and clearances were achieved in the as-welded condition, completed socket welds shall either be examined by postweld radiography oriented to verify the axial gap at the base of the socket weld, or they shall be examined in accordance with special instructions described in written procedures which comply with NB-5112.

NH-5262 Permanent Structural Attachment Welds

The rules of this paragraph shall be substituted for NB-5262.

(a) Permanent structural attachment welds, as defined in NB-4433, shall be examined by the methods listed below.

(1) radiography, unless it is excluded by (2) below. The absence of suitable radiographic equipment shall not be the justification for the rules of (2) below excluding the radiography requirements.

Page 62

(2) Where radiography is impractical, the requirements of (1) above may be replaced either by using ultrasonic examination on the completed weld, or by progressively examining the weld using the magnetic particle or the liquid penetrant method.

For progressive examination of multipass welds whose final thickness will be 1 in. (25 mm) or less, the examination shall be performed after completion of one-half the final weld thickness. For progressive examination of welds whose final weld thickness will exceed 1 in., examinations shall be performed after the completion of each $\frac{1}{2}$ in. (13 mm) of weld thickness.

(3) Completed weld surfaces shall be examined by either a magnetic particle method or a liquid penetrant method.

(b) If it becomes necessary to cool a partially completed weld in order to perform the progressive examination of (a)(2) above, then care should be taken to keep the large structural parts from imposing large tensile loadings on partially completed welds.

NH-5263 Nonstructural and Temporary Attachments

All completed weld surfaces on welds of nonstructural and temporary attachments, as defined in NB-4435, shall be examined by either a liquid penetrant or magnetic particle method.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NH-6000

ARTICLE NH-6000 TESTING

Page 63

Page 64

NH-6100 GENERAL REQUIREMENTS

Testing of Section III, Division I, Class 1 components when metal temperatures exceed those for which allowable stress values are given in Section II, Part D, shall be in accordance with the rules of this Subsection.

NH-6110 SCOPE OF TESTING

NH-6111 General Hydrostatic and Pneumatic Test Media

(a) The selection of a particular test medium may depend upon considerations in (b), (c), and (d) below. For some items, a combination of gaseous and liquid test media may be desirable.

(b) Compared to pressurized liquids, gas under a similar pressure has a greater potential energy release. It is therefore recommended that special precautions for protection of personnel be taken when a gas under pressure is used as a test medium.

(c) Some components, appurtenances, or systems are not designed to support the liquid weight required in a hydrotest. Pneumatic tests should be considered for such components.

(d) The use of liquids for testing often results in traces of the liquid left in hard-to-clean places in the system, and these residues may be harmful to the structural material because of reactions involving the residues and the system coolant. Pneumatic tests should be considered under these circumstances.

NH-6112 Pressure Testing of Components and Appurtenances

(a) Except as noted in (b) and (c) below, all components and appurtenances for elevated temperature service shall be static pressure tested in the presence of the Inspector.

(b) Nuts, bolts, studs, and gaskets are exempt from the rules of this Subsection.

(c) A static pressure test of each line valve and pump with inlet piping connections of 4 in. nominal pipe size and smaller shall be performed by the Manufacturer and so noted on the Data Report Form; however, this static pressure test need not be witnessed by the Inspector. The Inspector's review of the Manufacturer's test records will be his authority to sign the report. This takes precedence over NCA-5280.

(d) Under the special conditions of NH-6117 and NH-6118, a helium mass spectrometer leak test (plus other tests) may replace the static pressure test required in (a) above.

(e) The requirements of (a) above are met by meeting the requirement of NH-6113(a).

(f) The component or appurtenance pressure test, when conducted in accordance with the rules of NH-6221 or NH-6321, shall be acceptable as a pressure test for parts and piping subassemblies.

(g) For components and appurtenances which will be subjected to external pressure loads in service, the pressure test requirement in (a) above may be performed on the basis of an internal pressure test using the rules of NH-6221 or NH-6321. The Design Specifications may require further tests to demonstrate structural integrity under external pressure loading.

NH-6113 Pressure Testing of Systems

(a) Prior to initial operation, the installed Class 1 system shall be static pressure tested in the presence of the Inspector.

(b) Under the special restrictions of NH-6117 and NH-6118, a helium mass spectrometer leak test may replace the static pressure test in (a) above.

NH-6115 Time of Pressure Test and Stamping of Components and Appurtenances

(a) The pressure tests of components and appurtenances required by NH-6112(a) shall be performed

prior to installation in the system as specified in NH-6221(a) or NH-6321(a).

(b) The pressure tests of components and appurtenances required by NH-6112(a) may be performed after installation if the system pressure test is used under the provisions of NH-6221(c) or NH-6321(c).

(c) The Data Report Form shall not be completed nor signed by the Inspector and the components shall not be stamped until the component Manufacturer has conducted the static pressure test.

(d) Specially designed welded seals,¹ which are identified on the Data Report Form as being welded by the Installer under the rules of NH-6118, need not be tested prior to the stamping of the component.

(e) Appurtenances containing brazed joints, pumps not designed by detailed analysis,¹ and valves shall be static pressure tested prior to installation in a system.

NH-6116 Machining of Local Areas After Static Pressure Testing

(a) In local regions of the pressure boundary where tight tolerances are required for proper component functioning, extra wall thickness is permitted during pressure testing. If extra wall thickness is provided during fabrication, the excess material may be machined to critical dimensions and tolerances after completion of the static pressure test.

(b) The extra wall thickness permitted during pressure testing in (a) above shall not exceed 10% of the final wall thickness or $\frac{3}{8}$ in. (10 mm), whichever is less.

(c) The final wall thickness, after machining to critical dimensions and tolerances, shall comply with the minimum wall thickness requirements defined in the rules for design of Class 1 components for elevated temperature service.

NH-6117 Alternative Tests of Closure Welds and Access Hatches

(a) Closure welds for access hatches in vessels and closure welds for connecting piping subassemblies may be tested by an alternative procedure for the pressure test requirements of NH-6112 and NH-6113 provided the conditions of (1) through (4) below are met:

(1) If hydrotesting were to be used, residues from the hydrotest liquid could be deleterious to the service;

¹ Definitions are contained in the rules governing the design of Class 1 components in elevated temperature service.

(2) Closure welds are located at least $3\sqrt{RT}$ from major structural discontinuities such as flanges, large nozzles, pumps, or valves. R is the mean radius and T is the nominal thickness of the thicker material adjacent to the weld;

(3) The alternative test procedure in (b) below is specified for the closure welds; and

(4) The closure welds to which the alternative tests shall be applied, and the alternative test procedure shall be included in the Design Specification. The closure welds to which the alternative test procedure has been applied shall be identified on the Data Report.

(b) As an alternative to the pressure test procedure, closure welds may be tested by a mass spectrometer helium leak test.

NH-6118 Alternative Tests at Specially Designed Welded Seals

(a) Specially designed welded seals, such as omega and canopy seals, need not meet the pressure test requirements of NH-6112 and NH-6113 when:

(1) The final weld cannot be completed until after the hydrostatic or pneumatic test because the system test pressure would exceed the limit specified for any system component; and

(2) The seal is subjected to a leak test at the maximum normal operating pressure.

(b) Welds of specially designed welded seals may be tested by a helium leak test in lieu of the pressure test requirements of NH-6112 and NH-6113 provided:

(1) The welds of the seal, and the welds joining the seal to the component or supporting structure, cannot be visually examined during testing due to access restrictions; and

(2) The welds and the alternative test procedures have been mutually agreed to by the Owner and Manufacturer, and the requirements appear in the Design Specifications and in the Installer's Data Report Forms.

NH-6120 PREPARATION FOR TESTING

NH-6121 Exposure of Joints

All mechanical and welded joints, including welds, shall be left uninsulated and exposed for examination during the test.

NH-6122 Addition of Temporary Supports

Components designed for vapor or gas may be provided with additional temporary supports, if necessary, to support the weight of the test liquid.

Page 67

NH-6123 Restraint or Isolation of Expansion Joints

Expansion joints shall be provided with temporary restraint, if required for the additional pressure load under test, or they shall be isolated from the test.

NH-6124 Isolation of Equipment Not Subjected to Pressure Test

Equipment that is not to be subject to the pressure test shall be either disconnected from the component or system, or isolated by a blank flange or similar means. Valves may be used if the valve with its closure is suitable for the proposed test pressure.

NH-6125 Treatment of Flanged Joints Containing Blinds

Flanged joints at which blinds are inserted to blank off other equipment during the test need not be tested until the blinds are removed.

NH-6126 Precautions Against Test Medium Expansion

If a pressure test is to be maintained for a period of time and the test medium in the system is subject to thermal expansion, precautions shall be taken to avoid excessive pressure. A small relief valve set to 1.33 times the test pressure is recommended during the pressure test.

NH-6200 HYDROSTATIC TESTS

NH-6210 HYDROSTATIC TESTING PROCEDURE

NH-6211 Provision of Air Vents at High Points

Vents shall be provided at all high points of the component or system in the position in which the test is to be conducted to purge air pockets while the component or system is filling.

NH-6212 Test Medium and Test Temperature

(a) Any nonhazardous liquid at any temperature below its boiling point may be used for the hydrostatic test. Combustible liquids having a flash point less than 100°F, such as petroleum distillates, may be used only for tests at near atmospheric temperature.

(b) No hydrostatic test shall be performed at a temperature which exceeds those for which S_m values are listed in Tables 2A and 2B of Section II, Part D, Subpart 1 for any of the materials used in the pressure boundaries of components being tested.

(c) It is recommended that the test be made at a temperature that will minimize the possibility of brittle fracture (NB-2330). The test pressure shall not be applied until the component, appurtenance or system, and the pressurizing medium are

approximately at the same temperature.

(d) For the vessel hydrostatic test before installation, it is recommended that the test be made at a temperature not lower than $[RT_{NDT} + 60^{\circ}\text{F}]$, (NB-2331).

NH-6213 Check of Test Equipment Before Applying Pressure

The test equipment shall be examined before pressure is applied to ensure that it is tight and that all low pressure filling lines and other appurtenances that should not be subjected to the test pressures have been disconnected or isolated by valves or other suitable means.

NH-6215 Examination for Leakage After Application of Pressure

Following the application of the hydrostatic test pressure for a minimum of 10 minutes, as required by NH-6224, examination for leakage shall be made of all joints, connections, and of all regions of high stress such as regions around openings and thickness transition sections. Except in the case of pumps and valves, which shall be examined while at test pressure, this examination shall be made at a pressure equal to the greater of the design pressure or three-fourths of the test pressure and it shall be witnessed by the Inspector. Leakage of temporary gaskets and seals, installed for the purpose of conducting the hydrostatic test and which will be replaced later, may be permitted unless the leakage exceeds the capacity to maintain system test pressure for the required amount of time. Other leaks, such as from permanent seals, seats, and gasketed joints in components, may be permitted when specifically allowed by the Design Specifications. Leakage from temporary seals or leakage permitted by the Design Specifications shall be directed away from the surface of the component to avoid masking leaks from other joints.

Page 68

NH-6220 HYDROSTATIC TEST PRESSURE REQUIREMENTS

NH-6221 Minimum Required System Hydrostatic Test Pressure

(a) Except as may be otherwise required by material specifications and by the requirements of NH-6223, all components and appurtenances shall be subjected to a hydrostatic test at a pressure not less than 1.25 times the system design pressure prior to installation in the nuclear power system.

(b) All pressure retaining components of the completed Class 1 system shall be subjected to a system hydrostatic test at a pressure not less than 1.25 times the system design pressure unless specifically excepted under the provisions of NH-6117 and NH-6118.

(c) The system hydrostatic test of NH-6221(b) may be substituted for a component hydrostatic test of NH-6221(a) provided:

(1) The component can be repaired by welding, if required, as a result of the system hydrostatic test, in accordance with the rules of NB-2500;

(2) The component repair can be postweld heat treated, if required, and nondestructively examined in accordance with rules of NB-2500, NB-5100, and NB-5400, as applicable, subsequent to the system hydrostatic test; and

(3) The component is subjected to the required system hydrostatic test following the completion of repair and examination.

NH-6222 Maximum Permissible Hydrostatic Test Pressure

(a) The stress limits, contained in the rules of NH-3000, shall be used in determining the permissible hydrostatic test pressure. In multichamber components, pressure may be simultaneously applied to the appropriate adjacent chamber to meet these stress limits. The number of test sequences for which the above provisions may be considered applicable shall not exceed ten.

(b) When hydrostatically testing a system, the test pressure shall not exceed the lowest of the maximum test pressures allowed for any of the components in the system.

NH-6223 Hydrostatic Test Pressure for Valves, Pumps, and for Components and Appurtenances Containing Brazed Joints

(a) Prior to installation, valves, pumps not designed by detailed stress analysis, and other components and appurtenances containing brazed joints shall be hydrostatically tested at a pressure 1.5 times the system design pressure.

(b) The inlet (primary pressure containing) portion of safety and safety relief valves shall be hydrostatically tested at a pressure at least 1.5 times the set pressure marked on the valve. For closed system applications, the outlet portion of safety and safety relief valves shall be hydrostatically tested to 1.5 times the design secondary pressure of the outlet system.

NH-6224 Hydrostatic Test Pressure Holding Time

The hydrostatic test pressure shall be maintained for a minimum total time of 10 minutes and for such additional time as may be necessary to conduct the examination for leakage required by NH-6215. When testing pumps, valves, and other components covered by NH-6223, the pressure shall be maintained a minimum of 15 minutes for each inch of design minimum wall thickness, but for not less than 10 minutes.

NH-6300 PNEUMATIC TESTS

NH-6310 PNEUMATIC TESTING PROCEDURES

NH-6311 General Requirements

When a pneumatic test is performed, it shall be conducted in accordance with the requirements of NH-6300 and NH-6112.

NH-6312 Test Medium and Test Temperature

(a) The gas used as the test medium shall be non-flammable;

(b) It is recommended that the test be made at a temperature that will minimize the possibility of brittle fracture (NB-2330). The test pressure shall not be applied until the component, appurtenance or system, and the pressurizing medium are approximately the same temperature.

NH-6313 Check of Test Equipment Before Applying Pressure

The test equipment shall be examined before pressure is applied to ensure that it is tight and that all appurtenances that should not be subjected to the test pressure have been disconnected or isolated by valves or other suitable means.

Page 69

NH-6314 Procedure for Applying Pressure

The pressure in the system shall gradually be increased to not more than one-half of the test pressure, after which the pressure shall be increased in steps of approximately one-tenth of the test pressure until the required test pressure has been reached. The pressure shall then be reduced to a value equal to the greater of the design pressure or three-fourths of the test pressure and held for a sufficient time to permit examination of the system in accordance with NH-6315.

NH-6315 Examination for Leakage After Application of Pressure

Following the application of pressure for the time specified in NH-6324, examination of leakage in accordance with NH-6215 shall be made.

NH-6320 PNEUMATIC TEST PRESSURE REQUIREMENTS

NH-6321 Minimum Required System Pneumatic Test Pressure

(a) Except as may be otherwise required by material specifications and by the requirements of NH-6323, all components

and appurtenances shall be subjected to a pneumatic test at a pressure not less than 1.20 times the system design pressure prior to installation in the nuclear power system.

(b) All pressure retaining components of the completed Class 1 system shall be subjected to a system pneumatic test at a pressure not less than 1.20 times the system design pressure unless specifically excepted under the provisions of NH-6117 and NH-6118.

(c) The system pneumatic test of NH-6321(b) may be substituted for a component pneumatic test of NH-6321(a) provided:

(1) The component can be repaired by welding, if required as a result of the system pneumatic test, in accordance with the rules of NB-4400;

(2) The component repair can be postweld heat treated, if required, and nondestructively examined in accordance with the rules of NB-4400, NB-5100, and NB-5400, as applicable, subsequent to the system pneumatic test; and

(3) The component is subjected to the required system pressure test following the completion of repair and examination.

NH-6322 Maximum Permissible Pneumatic Test Pressure

(a) The stress limits contained in the rules of NH-3000 shall be used in determining the permissible pneumatic test pressure. In multichamber components, pressure may be simultaneously applied to the appropriate adjacent chamber to meet these stress limits. The number of test sequences for which the above provisions may be considered applicable shall not exceed ten.

(b) When pneumatically testing a system, the test pressure shall not exceed the lowest of the maximum test pressures allowed for any of the components in the system.

NH-6323 Pneumatic Test Pressure for Valves, Pumps, and for Components and Appurtenances Containing Brazed Joints

(a) Prior to installation, valves, pumps not designed by detailed stress analysis, and other components and appurtenances containing brazed joints shall be pneumatically tested at a pressure 1.5 times the system design pressure.

(b) The inlet (primary pressure containing) portion of safety and safety relief valves shall be pneumatically tested at a pressure at least 1.5 times the set pressure marked on the valve. For closed system applications, the outlet portion of safety and safety relief valves shall be pneumatically tested to 1.5 times the design secondary pressure of the outlet system.

NH-6324 Pneumatic Test Pressure Holding Time

The pneumatic test shall be maintained for a minimum total time of 10 minutes and for such additional time as may be necessary to conduct the examination for leakage required by NH-6215.

NH-6400 PRESSURE TEST GAGES

The rules of NB-6400 shall apply.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NH-7000

ARTICLE NH-7000 OVERPRESSURE PROTECTION

Page 71

Page 73

NH-7100 GENERAL REQUIREMENTS

Overpressure protection for Section III, Class 1 components, when the metal temperature exceeds the Applicability and Max. Temp. Limits listed in Section II, Part D, Tables 2A and 2B, shall be in accordance with the rules of NB-7000 except as modified by Subsection NH.

NH-7110 SCOPE

(a) Subsection NH provides Class 1 overpressure protection rules for those pressure boundary structures which, having been designated by the Owner (NCA-1140 and NCA-3230) as a group of items requiring such protection, are not covered by NB-7000 rules because some of the structures are expecting service temperatures above those currently allowed under the rules of Subsection NB.

(b) Whereas the rules of NB-7000 are oriented toward water and steam cooled reactor systems, the rules of Subsection NH encompass a wider variety of coolant fluids.

(c) The rules of NB-7000 shall govern unless paragraphs are specifically altered by the rules of Subsection NH. All references to other NB-7000 paragraphs are to be interpreted as referring to the NB-7000 paragraphs as modified by Subsection NH.

(d) As with NB-7000, the rules of this Subsection require that all system conditions, including transients, are described in the Design Specifications for the components being protected.

(e) In the evaluation of the effects of overpressure events, structural loadings shall include, but not be limited to, the types of events listed below.

(1) system overpressure due to a closed valve, a blocking object, or a solid core of metal coolant;

(2) overpressure due to the addition of heat to an isolated portion of the system;

(3) overpressure due to nuclear transients;

(4) overpressure due to failure of a system component, including the effects of leaks from adjacent systems and possible resulting chemical reactions;

(5) overpressure resulting from operator error;

(6) overpressure due to constant pressure in combination with a rising overtemperature condition;

(7) overpressure due to pump overspeed.

(f) Events whose overpressure effects are beyond the Scope of the rules of Subsection NH are covered by NB-7110(b) and include, for example:

(1) Rapid closure of a check valve gate leads to fluid shock conditions in a local region;

(2) Earthquake motions induce sloshing of fluids contained in large tanks;

(3) Nuclear incident induces a severe pressure spike in a local region;

(4) Rapid closure of a valve during high flow rate conditions introduces pressure shocks.

NH-7130 VERIFICATION OF THE OPERATION OF PRESSURE RELIEF DEVICES

Revise NB-7131 to read:

(a) Pressure relief devices shall be designed so that potential impairment of the overpressure protection function from service exposure to fluids can be determined by test or examination.

NH-7170 PERMITTED USE OF PRESSURE RELIEF DEVICES

Revise title of NB-7173 to read:

Valve Types Permitted for Water Service

Revise NB-7174 to read:

NB-7174 Nonreclosing Devices

Rupture disk devices may be used in air, gas, or liquid metal service in accordance with NB-7600.

Page 74

NH-7200 CONTENT OF OVERPRESSURE PROTECTION REPORT

Add to NB-7220, the listing below:

- (n) the effects of any thermal dissipation or discharge storage system on the pressure relief devices;
- (o) the disposition of effluent from pressure relief devices for both primary and secondary reactor coolant fluids.

NH-7300 RELIEVING CAPACITY

Revise NB-7321(c) to read:

The system overpressure established for setting the required total rated relieving capacity of (b) above shall be such that the calculated stress intensity and other design limitations for Service Limit C, as specified in the rules of NH-3000, are not exceeded for each of the components in the protected system.

NH-7600 NONRECLOSING PRESSURE RELIEF DEVICES

NH-7610 USE OF RUPTURE DISK DEVICES

Revise NB-7610 as shown below:

Rupture disk devices certified in accordance with NB-7720 may be used as sole protection against overpressure loadings. Rupture disks shall use materials of construction approved in NH-2000. Rupture disks may be used in conjunction with pressure relief valves on either the discharge side or the inlet side of the valve, provided the requirements of NB-7700 are met.

NH-7621 Provisions for Venting or Draining Near Rupture Disks

Revise NB-7621 as shown below:

The space between the rupture disk and any associated pressure relief valve shall be connected to a controlled disposal system as provided for the associated pressure relief valve. This space, if it exists, shall be provided with means to monitor its internal pressure during service periods.

Periodic and Related Phenomena			
frequency	hertz	Hz	revolutions per second (r/s)
rotational frequency	revolutions per second	s ⁻¹	revolutions per minute (r/m)
Mechanics			
mass	kilogram	kg	
density	kilogram per cubic meter	kg/m ³	
moment of inertia	kilogram · meter ²	kg · m ²	
force	newton	N	
moment of force (torque)	newton-meter	N · m	
pressure and stress	pascal	Pa	(pascal = newton per square meter)
energy, work	joule	J	kilowatt-hour (kW · h)
power	watt	W	
impact strength	joule	J	
section modulus	meter ³	m ³	
moment of section (second moment of area)	meter ⁴	m ⁴	
fracture toughness	Pa · √m		
Heat			
temperature — thermodynamic [Note (2)]	kelvin	K	degree Celsius (°C)
temperature — other than thermodynamic	degree Celsius	°C	kelvin (K)
linear expansion coefficient	meter per meter-kelvin	K ⁻¹	°C ⁻¹
quantity of heat	joule	J	
heat flow rate	watt	W	
thermal conductivity	watt per meter-kelvin	W/(m · K)	W/(m · °C)
thermal diffusivity	square meter per second	m ² /s	
specific heat capacity	joule per kilogram-kelvin	J/(kg · K)	J/(kg · °C)
Electricity and Magnetism			
electric current	ampere	A	
electric potential	volt	V	
current density	ampere per meter ²	A/m ²	
magnetic field strength	ampere per meter	A/m	

NOTES:

- (1) Conversion factors between SI units and U.S. customary are given in SI-1, "ASME Orientation and Guide for Use of SI (Metric) Units," and ASTM E 380.
- (2) Preferred use for temperature and temperature interval is degrees Celsius (°C), except for thermodynamic and cryogenic work where kelvins may be more suitable. For temperature interval, 1 K = 1°C exactly.

LIST OF SI UNITS FOR USE WITH ASME BOILER AND PRESSURE VESSEL CODE¹

COMMONLY USED CONVERSION FACTORS
(For Others See ASTM E 380) [See Note (1)]

Quantity	To Convert From	To	Multiply by [Note (2)]

power	hp (550 ft · lbf/s)	W	7.456 999	E+02
fracture toughness	ksi · $\sqrt{\text{in}}$	Pa · $\sqrt{\text{m}}$	1.098 843	E+06
temperature	°C	K	$t_K = t_C + 273.15$	
	°F	K	$t_K = (t_F + 459.67)/1.8$	
	°F	°C	$t_C = (t_F - 32)/1.8$	
temperature interval	°C	K	1.0*	E+00
	°F	K or °C	5.555 555	E-01

NOTES:

- (1) Care should be taken when converting formulas or equations that contain constant terms or factors. The value of these terms must be understood and may also require conversion.
- (2)(a) Relationships that are exact in terms of the base units are followed by a single asterisk.
- (b) The factors are written as a number greater than 1 and less than 10 with 6 or less decimal places. The number is followed by the letter E (for exponent), a plus or minus symbol, and two digits which indicate the power of 10 by which the number must be multiplied to obtain the correct value. For example: 3.523 907 E-02 is $3.523\ 907 \times 10^{-2}$ or 0.035 239 07.

	SA-691	Welded Pipe	Pipe 2¼ CR (SA-387, Gr. 22, Cl. 1)

NOTES:

- (1) These materials shall have a minimum specified room temperature yield strength of 30,000 psi and a minimum specified carbon content of 0.04%.
- (2) For use at temperatures above 1,000°F, these materials may be used only if the material is heat treated by heating to a minimum temperature of 1,900°F and quenching in water or rapidly cooling by other means.
- (3) Appendix X provides nonmandatory guidelines on additional specification restrictions to improve performance in certain service applications.
- (4) These materials shall have a total aluminum-plus-titanium content of at least 0.50% and shall have been heat treated at a temperature of 2,050°F or higher.
- (5) This material shall have a minimum specified room temperature yield strength of 30,000 psi, a minimum specified room temperature ultimate strength of 60,000 psi, a maximum specified room temperature ultimate strength of 85,000 psi, and a minimum specified carbon content of 0.07%.
- (6) The material allowed under SA-234 shall correspond to one of:
SA-335, Grade P 22
SA-387, Grade 22, Class 1
SA-182, Grade F 22, Class 1 in compliance with Note (4).

GENERAL NOTE:

The tabulated values of yield strength are those which are suitable for use in design calculations required by this Subsection. At temperatures above room temperature, the yield strength values correspond to the yield strength trend curve adjusted to the minimum specified room temperature yield strength. The yield strength values do not correspond exactly to either *average* or *minimum* as these terms are applied to a statistical treatment of a homogeneous set of data.

Neither the ASME Materials Specifications nor the rules of this Subsection require elevated temperature testing for yield strengths of production material for use in Code components. It is not intended that results of such tests, if performed, be compared with these tabulated yield strength values for ASME Code acceptance/rejection purposes for materials. If some elevated temperature test results on production material appear lower than the tabulated values by a large amount (more than the typical variability of material and suggesting the possibility of some error) further investigation by retests or other means should be considered.

GENERAL NOTE: If bolting temperatures do not exceed those given in Table 4 of Section II, Part D for the bolting material, the S_m values in Table 4 of Section II, Part D shall apply. For elevated temperatures, the list of materials shown below can be used in bolting applications.

NOTES:

- (1) For use at temperatures above 1,000°F, these materials may be used only if the material is heat treated by heating to a minimum temperature of 1,900°F and quenching in water or rapidly cooling by other means.
- (2) Maximum forging diameter shall be limited to 6 in.
- (3) Welding is not permitted.
- (4) Precautionary Note: In use of Alloy 718, consideration shall be given to a reduction in toughness caused by long-term exposure at a temperature of 1,000°F or greater.

APPENDIX T RULES FOR STRAIN, DEFORMATION, AND FATIGUE LIMITS AT ELEVATED TEMPERATURES

Page 107

T-1100 INTRODUCTION

T-1110 OBJECTIVE

The objective of this Appendix is to provide rules which may be used by Owners and N Certificate Holders with respect to evaluation by analysis of strain, deformation, and fatigue limits for components whose load controlled stresses are evaluated by the rules of Subsection NH.

T-1120 GENERAL REQUIREMENTS

T-1121 Type of Analysis

Where creep effects are presumed significant, inelastic analysis is generally required to provide a quantitative assessment of deformations and strains. However, elastic and simplified inelastic methods of analysis may sometimes be justified and used to establish conservative bounds for deformations, strains, strain ranges, and maximum stress in order to reduce the number of locations in a structure requiring detailed inelastic analysis.

T-1122 Analysis Required

The rules for design against gross distortion and fatigue are illustrated in Fig. NH-3221-1. The Design Loadings and Level D Service Loadings are exempted from strain and deformation limits as summarized below.

Loadings

Design

Service Levels A, B, and C

Requirement

No deformation analysis required.

Apply the strain and deformation limits of Appendix T.

Regions not expecting any service time under elevated temperatures may use the secondary stress and fatigue limits of

Service Level D	NB-3222.2 and NB-3222.4 in place of the rules in T-1300, T-1400, and T-1700.
Test	Strain and deformation limits not applicable except as necessary to satisfy Level D Service Loadings functional requirements. Consider as additional Level B Service Loadings.

T-1200 DEFORMATION LIMITS FOR FUNCTIONAL REQUIREMENTS

T-1210 STATEMENT IN DESIGN SPECIFICATION

Deformation limits to ensure proper component functioning shall be specified in the Design Specification (NCA-3250) for the component or shall be established by the N Certificate Holder for the proper performance of the component. Any such limits may restrict the design more severely than those specified for load controlled stresses in NH-3220.

T-1220 ELASTIC ANALYSIS METHOD

The limitations on loads from the rules and the other limits contained in NH-3200 are intended to restrict the accumulated inelastic strain (averaged across a wall thickness) to 1% or less. However, when elastic analysis is used, the occurrence of inelastic strains of this magnitude may not be apparent. If functional deformation requirements are specified, the designer shall ensure that they are not violated by assuming that strains of 1% occur within the structure in that distribution which leads to the worst possible deformation state consistent with the directions of loading. If this deformation state does not lead to deformations greater than the specified limits, then all functional requirements shall be considered as demonstrated for the design.

Page 114

T-1230 USE OF INELASTIC ANALYSIS

Inelastic analysis of deformations shall be used to demonstrate that deformations do not exceed specified limits, unless the elastic method of T-1220 has demonstrated compliance.

T-1300 DEFORMATION AND STRAIN LIMITS FOR STRUCTURAL INTEGRITY

T-1310 LIMITS FOR INELASTIC STRAINS

In regions expecting elevated temperatures, the maximum accumulated inelastic strain shall not exceed the following values.

- (a) strains averaged through the thickness, 1%;
- (b) strains at the surface, due to an equivalent linear distribution of strain through the thickness, 2%;
- (c) local strains at any point, 5%.

The above limits apply to computed strains accumulated over the expected operating lifetime of the element under consideration, and computed for some steady-state period at the end of this time during which significant transients are not occurring. These limits apply to the maximum positive value of the three principal strains. A positive strain is defined as one for which the length of the element in the direction of the strain is increased. The principal strains are computed for the strain components $(\epsilon_x, \epsilon_y, \epsilon_z, \epsilon_{xy}, \epsilon_{xz}, \epsilon_{yz})$. When the strain is computed at several locations through the thickness, the strains are first averaged and linearized on a component level and then combined to determine the principal strains for comparison to the limits on average and surface strains defined above. The limits for local strains are based on the computed strains at the point of interest.

T-1320 SATISFACTION OF STRAIN LIMITS USING ELASTIC ANALYSIS

T-1321 General Requirements

The strain limits of T-1310 are considered to have been satisfied if the limits of any one of T-1322, T-1323, or T-1324 are satisfied. The guidelines of (a) through (d) below should be used in establishing the appropriate cycle to be evaluated in T-1322 and T-1323.

(a) An individual cycle, as defined in the Design Specification, cannot be split into subcycles to satisfy these requirements.

(b) At least one cycle must be defined that includes the maximum secondary stress intensity range, Q_R , and the maximum value of $(P_L + P_b/K_t)$, which occur during *all* Level A, B, and C Service Loadings. The value of K_t may be determined using Eq. (6) of NH-3223.

(c) Any number of cycles can be grouped together and evaluated according to the conditions of T-1322 or T-1323, whichever is applicable.

(d) The following definitions apply to T-1322 and T-1323:

$$X \equiv \left(P_L + \frac{P_b}{K_t} \right)_{\max} \div S_y$$

where

$(P_L + P_b/K_t)_{\max}$

= the maximum value of the primary stress intensity, adjusted for bending via K_p , during the cycle being evaluated

S_y

= the average of the S_y values at the maximum and minimum wall averaged temperatures during the cycle being evaluated

$$Y \equiv \frac{(Q_R)_{\max}}{S_y}$$

where

$(Q_R)_{\max}$

= the maximum range of the secondary stress intensity during the cycle being considered

S_y

= the average of the S_y values at the maximum and minimum wall averaged temperatures during the cycle

T-1322 Test No. A-1

For Test Number A-1:

$$X + Y \leq S_a/S_y \quad (1)$$

(1)

where S_a is the lesser of:

(a) $1.25 S_t$ using the highest wall averaged temperature during the cycle and a time value of 10^4 hr, and

(b) the average of the two S_y values associated with the maximum and minimum wall averaged temperatures during the cycle

TABLE T-1323
TEMPERATURES AT WHICH $S_m = S_t 10^5$

Material	Temp., °F
Type 304 SS	948
Type 316 SS	1,011
Alloy 800H	1,064
2¼Cr-1Mo	801

TABLE T-1323 TEMPERATURES AT WHICH $S_m = S_t 10^5$

T-1323 Test No. A-2

For Test Number A-2:

$$X + Y \leq 1 \quad (2)$$

(2) for those cycles during which the average wall temperature at one of the stress extremes defining the maximum secondary stress range $(Q_R)_{\max}$ is below the applicable temperature of Table T-1323.

T-1324 Test No. A-3

For Test Number A-3, the limits of NB-3222.2, NB-3222.3, and NB-3222.5 shall be met and, in addition, the requirements of (a) through (d) below shall be satisfied.

(a)

$$\sum_i \frac{t_i}{t_{id}} \leq 0.1$$

where

t_i

= total duration of time during the service lifetime that the metal is at temperature, T_i . Note that the service lifetime shall never be greater than the sum of all t_i .

t_{id}

= maximum allowable time as determined by entering Figs. I-14.6 at temperature T_i and a stress value of 1.5 times the S_y associated with T_i , denoted as $1.5 S_{y|T_i}$. If $1.5 S_{y|T_i}$ is above the stress values provided in Figs. I-14.6, this test cannot be satisfied. When $1.5 S_{y|T_i}$ is below the lowest stress value provided in Figs. I-14.6, the constant temperature line may be extrapolated to larger t_{id} values using the steepest slope on Figs. I-14.6 for that material.

(b)

$$\sum \epsilon_i \leq 0.2\%$$

where ϵ_i is the creep strain that would be expected from a stress level of $1.25 S_y|_{T_i}$ applied for the total duration of time during the service lifetime that the metal is at T_i . When the design lifetime is separated into several time periods, then the service lifetime shall not be greater than the sum of all the time periods. That is:

$$\sum_i t_i|T_i \geq \text{service lifetime}$$

(c) For the $3S_m$ limit in NB-3222.2 and NB-3222.3, use the lesser of $3S_m$ and $3\bar{S}_m$, where

$3\bar{S}_m$

$= (1.5 S_m + S_{rH})$ when only one extreme of the stress difference [that produces the maximum range of the primary plus secondary stress intensity, $P + Q$] occurs at a temperature above those covered by Subsection NB rules;

$3\bar{S}_m$

$= (S_{rH} + S_{rL})$ when both extremes of the stress differences (that define the maximum range of $P + Q$) occur at temperatures above those covered by Subsection NB rules;

$S_{rH} S_{rL}$

$=$ relaxation strengths associated with the temperatures at the *hot* and *cold* extremes of the stress cycle. The *hot* temperature condition is defined as the maximum operating temperature of

the stress cycle. The *hot* time is equal to the portion of service life when wall averaged temperatures exceed 800°F (427°C) (700°F (371°C) for 2¹/₄Cr-1Mo). The *cold* temperature is defined as the colder of the two temperatures corresponding to the two stress extremes in the stress cycle. The *cold* time is again equal to the portion of service life when wall averaged temperatures exceed 800°F (700°F for 2¹/₄Cr-1Mo).

In this criterion, total service life may *not* be further subdivided into temperature-time blocks. The two relaxation strengths, S_{rH} and S_{rL} , may be determined by performing a pure uniaxial relaxation analysis starting with an initial stress of $1.5 S_m$ and holding the initial strain throughout the time interval equal to the time of service above 800°F (427°C) [700°F (371°C) for 2¹/₄Cr-1Mo].

(d) The reference to the endurance limit NB-3222.5(b) is not applicable to the materials in this Subsection.

Page 116

T-1325 Special Requirements for Piping Components

(a) Piping evaluations using the provisions of NH-3651(b) to satisfy the limits of T-1322, T-1323, or T-1330 shall include the stress term:

$$\frac{E \propto |\Delta T_1|}{2(1 - \nu)}$$

when computing the secondary stress intensity range, Q_R . The definitions of E , α , ΔT_1 , and ν , are as given in NB-3650.

(b) For purposes of applying the limits of T-1324 to piping components, satisfaction of the NB-3650 requirements may be used in lieu of meeting NB-3222.2, NB-3222.3, and NB-3222.5, provided that S_m is replaced by $\bar{S}_m$ and the ratchet check of NB-3653.7 is satisfied whenever:

$$S_n > 3\bar{S}_m - \frac{E \propto |\Delta T_1|}{2(1 - \nu)}$$

S_n , E , α , ΔT , and ν are defined in NB-3650, and $\bar{S}_m$ is the lesser of S_m or $(3\bar{S}_m) \div 3$, with $3\bar{S}_m$ as defined in T-1324(c).

T-1330 SATISFACTION OF STRAIN LIMITS USING SIMPLIFIED INELASTIC ANALYSIS

T-1331 General Requirements

The strain limits of T-1310 are considered to have been satisfied if the limits of T-1332 are satisfied in addition to (a) through (g) below.

(a) T-1332 contains two tests, B-1 and B-2. Test B-1 can be used only for:

- (1) axisymmetric structures subjected to axisymmetric loadings and away from local structural discontinuities; or
- (2) general structures in which the peak through-the-wall thermal stress is negligible (i.e., the thermal stress distribution is linear through the wall).

Test B-2, which is more conservative, is applicable to any structure and loading.

(b) The individual cycle as defined in the design specification cannot be split into subcycles. Unless otherwise specified (see NH-3114), earthquakes and other transient conditions should be uniformly distributed over the lifetime of the plant for this strain evaluation.

(c) As an alternate to the use of T-1332, the inelastic strains due to any number of selected operational cycles may be evaluated separately by T-1333 or using detailed inelastic analysis. The resulting sum of the inelastic strains must satisfy the limits of T-1310. T-1333 is applicable only to axisymmetric structures subjected to axisymmetric loadings and away from local structural discontinuities.

(d) Secondary stresses with elastic followup (i.e., pressure induced membrane and bending stresses and thermal induced membrane stresses) are classified as primary stresses for purposes of this evaluation. Alternatively, the strains due to such stresses may be calculated separately and added to the strains from T-1332 and T-1333, the sum being limited to the values of T-1310. If the latter is done, stresses with elastic follow-up should be treated as secondary in the σ_c evaluation.

(e) The time used in T-1332 to enter the isochronous curves for individual cycles or timeblocks shall always sum to the entire life regardless of whether all or only part of the cycles are evaluated under these procedures.

(f) For T-1332, the definitions of X and Y in T-1321(d) apply except that the S_y value is replaced by the S_{yL} value which corresponds to the lower of the wall averaged temperatures for the stress extremes defining the secondary stress range, Q_R . The S_{yH} value corresponds to the higher of the wall averaged temperatures for the stress extremes defining the secondary stress range. The above defined extremes denoted by subscripts L and H are also referred to later as the cold and hot ends respectively.

(g) For T-1333, the definitions of X and Y in T-1321(d) apply, but X_L , Y_L , X_H and Y_H are calculated for the cold and hot ends using S_{yL} and S_{yH} respectively.

(h) When applying the procedures of T-1332 (Test No. B-1) and T-1333, wall membrane forces from overall bending of a pipe section or vessel can be conservatively included as axisymmetrical forces.

T-1332 Test Nos. B-1 and B-2

(a) These tests can be used to satisfy the strain limits provided that the average wall temperature at one of the stress extremes defining each secondary stress intensity range Q_R is below the applicable temperature of Table T-1323. The limits of this paragraph restrict the amount of inelastic creep strain that can be accumulated over the service life of the component including Levels A, B, and C Service Loadings so that the strain limits of T-1310 are not exceeded. In this paragraph, the elastically calculated primary and secondary stress intensities are used to determine an effective creep stress $\sigma_e = Z \cdot S_{yL}$ which in turn is used to determine a

Page 117

total ratcheting creep strain. The dimensionless effective creep stress parameter Z for any combination of loading is given in Fig. T-1332-1 for Test No. B-1 and in Fig. T-1332-2 for Test No. B-2.

(b) The creep ratcheting strain is determined by multiplying σ_e by 1.25 and evaluating the creep strain associated with the $1.25 \sigma_e$ stress held constant throughout the temperature-time history of the entire service life. The isochronous stress-strain curves of T-1800 shall be used to obtain the creep ratcheting strain. The total service life may be subdivided into temperature-time blocks. The value of σ_e may differ from one block to another, but remains constant throughout each block service time. When σ_e is reduced at the end of a block of loading, the time of the block of loading must be longer or equal to the time needed for σ_e to relax at constant total strain to the σ_e value for the subsequent block. The creep strain increment for each block may be evaluated separately. The times used in selecting the isochronous curves shall sum to the total service life. For each block, the isochronous curves can be entered at the initial strain accumulated throughout the prior load history. The creep strain increments for each time-temperature block shall be added to obtain the total ratcheting creep strain. The resulting value shall be limited to 1% for parent metal and $1/2\%$ for weld metal.

(c) The dimensionless expressions for the effective creep stress parameter is $Z = \sigma_e / S_{yL}$ in regimes S_1 , S_2 and P of Fig. T-1332-1, and:

$$(3) Z = X \cdot Y$$

in regimes S_2 and P , and:

$$(4) Z = Y + 1 - 2\sqrt{(1-X)Y}$$

in regime S_1 . In regime E , $Z = X$. The equations defining the boundaries of the regimes P , S_1 , and S_2 are shown in Fig. T-1332-1. Test No. B-1 can only be applied when σ_e is less than the yield stress of S_{yH} (see regimes E , S_1 , S_2 and P).

(d) For Test No. B-2, the effective creep stress σ_e shall be obtained from Fig. T-1332-2.

T-1333 Test No. B-3

(a) The procedure of T-1333 may be used for cycles in regimes R_1 and R_2 . This procedure may also be applied to cycles in the S_1 , S_2 and P regimes in order to minimize the conservatism in the calculated strains when there are a few relatively severe cycles. For cycles evaluated using T-1333, the resulting plastic ratchet strains and the enhanced creep strains due to creep relaxation within these cycles must be added to strains bounded by T-1332, Test No. B-1. The total inelastic strains accumulated in the lifetime of the component are given by:

$$\Sigma \epsilon = \Sigma \nu + \Sigma \eta + \Sigma \delta \quad (5)$$

(5)

where

$\Sigma \delta$	= the enhanced creep strain increments due to relaxation of the $[\sigma_c]$ stresses, obtained as explained in T-1333(c)
$\Sigma \eta$	= the plastic ratchet strain increments for cycles in regimes S_1 , S_2 , P , R_1 , and R_2 , obtained as explained in T-1333(b)
$\Sigma \nu$	= the inelastic strains obtained from the isochronous curves as in Test No. B-1 of T-1332, ignoring the increase of σ_c stress for cycles evaluated using T-1333 and detailed inelastic analyses

(b) Plastic ratcheting occurs in cycles when $[\sigma_{cL}] \geq S_{yH}$. The increment of plastic ratchet strain within this cycle is bounded by:

$$\eta_{(n)} = \frac{1}{E_H} \left[([\sigma_{cL}] - S_{yH}) + ([\sigma_{cH}] - S_{yL}) \right] \quad (6)$$

(6) (hot extreme only in regimes S_1 and R_2) for $Z_L < 1.0$, or:

$$\eta_{(n)} = \frac{1}{E_L} ([\sigma_{cL}] - S_{yL}) + \frac{1}{E_H} ([\sigma_{cH}] - S_{yH}) \quad (7)$$

(7) (both extremes in regimes R_1 and R_2) for $Z_L > 1.0$. $[\sigma_{cL}]$ and $[\sigma_{cH}]$ are the effective stresses for the cold and hot extremes of the cycles as given by $[\sigma_{cL}] = Z_L S_{yL}$ and $[\sigma_{cH}] = Z_H S_{yH}$ respectively.

The effective creep stress parameter Z is obtained from Eq. (3) for regimes S_2 , P , and R_2 . Equation (4) is for regimes S_1 and R_1 . Curves resulting from Eqs. (3) and (4) are shown in Fig. T-1332-1. Note that braces indicate $[\sigma_c]$ stress calculated for T-1333 evaluations. E_L and E_H are the elastic moduli at the cold and hot ends of the cycle.

Note that all values in Eqs. (6) and (7) are related to the load cycle (n).

(c) For cycles where $[\sigma_{cL}] \geq S_{yH}$ the enhanced creep strain increment due to stress relaxation is given by:

$$\delta_{(n)} = \frac{1}{E_H} \frac{S_{yH}^2 - \sigma_c^2}{\sigma_c} \quad (8)$$

(8)

For cycles where $[\sigma_{cL}] < S_{yH}$ the enhanced creep

Page 118

Page 119

FIG. T-1332-1 EFFECTIVE CREEP STRESS PARAMETER Z FOR SIMPLIFIED INELASTIC ANALYSIS USING TEST NOS. B-1 AND B-3
[For Use Only When the Restrictions of T-1331(a) for Test No. B-1 Are Met]

strain increment due to $[\sigma_{cL}]$ stress relaxation is given by:

FIG. T-1332-2 EFFECTIVE CREEP STRESS PARAMETER Z FOR SIMPLIFIED INELASTIC ANALYSIS USING TEST NO. B-2
(Applicable to General Structures)

FIG. T-1332-2 EFFECTIVE CREEP STRESS PARAMETER Z FOR SIMPLIFIED INELASTIC ANALYSIS USING TEST NO. B-2

$$\delta_{(n)} = \frac{1}{E_H} \frac{[\sigma_{cL}]^2 - \sigma_c^2}{\sigma_c} \quad (9)$$

(9)

σ_c is the effective creep stress from T-1332 for the next cycle when sequence of loading is specified. Otherwise, the lowest σ_c stress used in the T-1332 evaluation should be used in Eqs. (8) and (9).

Note that all values in Eqs. (8) and (9) are related to the load cycle (n). Only positive $\delta_{(n)}$ increments should be considered.

T-1400 CREEP-FATIGUE EVALUATION

T-1410 GENERAL REQUIREMENTS

T-1411 Damage Equation

The combination of Levels A, B, and C Service Loadings shall be evaluated for accumulated creep and fatigue damage, including hold time and strain rate effects. For a design to be acceptable, the creep and fatigue damage shall satisfy the following relation:

$$\sum_{j=1}^P \left(\frac{n}{N_d} \right)_j + \sum_{k=1}^q \left(\frac{\Delta t}{T_d} \right)_k \leq D \quad (10)$$

(10)

where

D

= total creep-fatigue damage

(N_{dj})

= number of design allowable cycles for cycle type, j , determined from one of the design fatigue curves (Figs. T-1420-1) corresponding to the maximum metal temperature occurring during the cycle. The design fatigue curves were determined from completely reversed loading conditions at strain rates greater than, or equal to, those noted on the curves.

(T_{dk})

= allowable time duration determined from Figs. I-14.6 (stress-to-rupture curves) for a given stress and the maximum temperature at the point of interest and occurring during the time interval, k . For elastic analysis, the appropriate stress measure is defined in T-1433. For inelastic analysis, the following equivalent stress quantity should be used:

$$\sigma_e = \bar{\sigma} \exp \left[C \left(\frac{J_1}{S_s} - 1 \right) \right]$$

where

$$J_1 = \sigma_1 + \sigma_1 + \sigma_3$$

$$S_s = [\sigma_1^2 + \sigma_2^2 + \sigma_3^2]^{1/2}$$

$$\sigma_{\text{eff}} = \frac{1}{\sqrt{2}} [(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2]^{1/2}$$

and σ_i are the principal stresses. The constant C is equal to 0.24 for Types 304 and 316 stainless steels; for Alloy 800H and 2 $\frac{1}{4}$ Cr-1Mo steel, the value is 0.0. For both types of analysis, the allowable time duration is determined by entering Figs. I-14.6 at that stress value determined by dividing the maximum stress (at the point of interest during the time interval, k) by the factor, K' (Table T-1411-1).

$(n)_j$

= number of applied repetitions of cycle type, j

q

= number of time intervals (each with a unique stress-temperature combination) needed to represent the specified elevated temperature service life at the point of

$(\Delta t)_k$

interest for the creep damage calculation

= duration of the time interval, k

TABLE T-1411-1

Material	K'
Austenitic Stainless Steel	0.67
Ni-Fe-Cr (Alloy 800H)	0.67
2¼Cr-1Mo	0.67

TABLE T-1411-1

Note that the sum of the "q" time intervals must equal or exceed the total specified elevated temperature service life.

T-1412 Exemption From Fatigue Analysis

The rules in NB-3222.4(d) which permit exemption from fatigue analysis do not apply to temperatures above the limits of Subsection NB except where the service loadings have been qualified as not introducing significant time-dependent effects under the procedure of NH-3211(c).

Page 121

T-1413 Equivalent Strain Range

An equivalent strain range is used to evaluate the fatigue damage sum for both elastic and inelastic analysis. When the Design Specification contains a histogram delineating a specific loading sequence, the strain range shall be calculated for the cycles described by the histogram. If the sequence of loading is not defined by the Design Specification, then the method of combining cycles described in NB-3222.4(e)(5) shall be applied. The equivalent strain range is computed as follows.

Step 1: Calculate all strain components for each point, i , in time $(\epsilon_{x\bar{i}}, \epsilon_{y\bar{i}}, \epsilon_{z\bar{i}}, \gamma_{xy\bar{i}}, \gamma_{yz\bar{i}}, \gamma_{zx\bar{i}})$ for the complete cycle. When conducting inelastic analysis, the stress and strain concentration effects of local geometric discontinuities are included in this step. When conducting elastic analysis, peak strains arising from geometric discontinuities are not included, since these effects are added in the procedures of T-1432.

Step 2: Select a point when conditions are at an extreme for the cycle, either maximum or minimum. Refer to this time point by a subscript o .

Step 3: Calculate the history of the change in strain components by subtracting the values at the time, o , from the corresponding components at each point in time, i , during the cycle.

$$\Delta \epsilon_{xi} = \epsilon_{xi} - \epsilon_{xo}$$

$$\Delta \epsilon_{yi} = \epsilon_{yi} - \epsilon_{yo}$$

etc;

Step 4: Calculate the equivalent strain range for each point in time as:

$$\Delta \epsilon_{\text{equiv. } i} = \frac{\sqrt{2}}{2(1 + \nu^*)} \left[(\Delta \epsilon_{xi} - \Delta \epsilon_{yi})^2 + (\Delta \epsilon_{yi} - \Delta \epsilon_{zi})^2 + (\Delta \epsilon_{zi} - \Delta \epsilon_{xi})^2 + \frac{3}{2} (\Delta \gamma_{xyi}^2 + \Delta \gamma_{yzi}^2 + \Delta \gamma_{zxi}^2) \right]^{1/2} \quad (11)$$

(11)

where

v^* = 0.5 when using the rules of T-1420

v^* = 0.3 when using the rules of T-1430

Step 5: Define $\Delta\epsilon_{\max}$ as the maximum value of the above calculated equivalent strain ranges, $\Delta\epsilon_{\text{equiv},i}$

The above five step procedure may be used regardless of whether principal strains change directions. When principal strains do not rotate, an alternative to the above sequence is given in T-1414.

T-1414 Alternative Calculation Method - Equivalent Strain Range

An alternative calculational method for equivalent strain range determination - applicable only when principal strains do not rotate - is as follows:

Step 1: No change from Step 1 of T-1413.

Step 2: Determine the principal strains versus time for the cycle.

Step 3: At each time interval of Step 2, determine the strain differences $\epsilon_1 - \epsilon_2$, $\epsilon_2 - \epsilon_3$, $\epsilon_3 - \epsilon_1$.

Step 4: Select a point when conditions are at an extreme for the cycle, either maximum or minimum. Refer to this time point by a subscript o .

Step 5: Determine the history of the change in strain differences by subtracting the values at the time, o , from the corresponding values at each point in time, i , during the cycle. Designate these strain difference changes as:

$$\Delta(\epsilon_1 - \epsilon_2)_i = (\epsilon_1 - \epsilon_2)_i - (\epsilon_1 - \epsilon_2)_o$$

$$\Delta(\epsilon_2 - \epsilon_3)_i = (\epsilon_2 - \epsilon_3)_i - (\epsilon_2 - \epsilon_3)_o$$

$$\Delta(\epsilon_3 - \epsilon_1)_i = (\epsilon_3 - \epsilon_1)_i - (\epsilon_3 - \epsilon_1)_o$$

Step 6: For each time point, i , calculate the equivalent strain range as:

$$\Delta \epsilon_{\text{equiv. } i} = \frac{\sqrt{2}}{2(1 + \nu^*)} \left\{ [\Delta (\epsilon_1 - \epsilon_2)_i]^2 + [\Delta (\epsilon_2 - \epsilon_3)_i]^2 + [\Delta (\epsilon_3 - \epsilon_1)_i]^2 \right\}^{1/2}$$

where ν^* is defined as in T-1413.

Step 7: Define $\Delta \epsilon_{\text{max}}$ as the maximum value of the above calculated equivalent strain ranges, $\Delta \epsilon_{\text{equiv. } i}$.

Page 122

T-1420 LIMITS USING INELASTIC ANALYSIS

When inelastic analysis is used to satisfy the requirements of T-1411, the rules of (a), (b), and (c) below apply.

(a) The creep damage term of Eq. (10) may also be calculated by using the integral form:

$$\int_0^t \frac{dt}{T_d}$$

(b) The fatigue damage term of Eq. (10) is evaluated by entering a design fatigue curve at the strain range ϵ_f . The strain range ϵ_f is defined as $\epsilon_f = \Delta \epsilon_{\text{max}}$; where $\Delta \epsilon_{\text{max}}$ is the value calculated in either T-1413 or T-1414. The appropriate design fatigue curve is selected from Figs. T-1420-1 and corresponds to the maximum metal temperature experienced during the

cycle.

(c) The total damage, D , shall not exceed the creep-fatigue damage envelope of Fig. T-1420-2.

T-1430 LIMITS USING ELASTIC ANALYSIS

T-1431 General Requirements

(a) The elastic analysis rules in this paragraph may be used only when:

- (1) the elastic ratcheting rules of T-1320 or T-1330 with Z less than, or equal to, 1.0 have been satisfied;
- (2) the $3S_m$ limit in NB-3222.2 is met using for $3S_m$ the lesser of $3S_m$ and $3\bar{S}_m$ as defined in T-1324; and
- (3) pressure induced membrane and bending stresses and thermal induced membrane stresses are classified as primary (load controlled) stresses.

The secondary stress range due to radial thermal gradients may be excluded from $(Q_R)_{\max}$ in either T-1322 or T-1323 in determining the applicability of elastic creep-fatigue rules.

(b) Linearly elastic analysis methods may significantly underestimate the actual strain range incurred during plastic or creep deformation. The method of T-1432 may be used to account for these increased strain ranges due to inelastic behavior in the region under consideration. The resulting strain range, ϵ_p , is used to enter a design fatigue curve to evaluate the fatigue damage term of Eq. (10). The appropriate design fatigue curve is selected from Figs. T-1420-1 and corresponds to the maximum metal temperature occurring during the cycle.

(c) The creep damage term of Eq. (10) is evaluated using the procedure of T-1433.

(d) The total damage, D , shall not exceed the creep-fatigue damage envelope of Fig. T-1420-2.

T-1432 Strain Range Determination

(a) Calculate $\Delta\epsilon_{\max}$ using T-1413 or T-1414. The strain components to be used in T-1413 or T-1414 are elastically calculated and do not include local geometric stress concentration effects. Alternatively, calculate $\Delta\epsilon_{\max}$ using the stress difference procedure described in NB-3216. However, for the purpose of calculating $\Delta\epsilon_{\max}$, the effects of local geometric stress concentrations are omitted. The strain range $\Delta\epsilon_{\max}$ is defined as equal to $2S_{\text{alt}}/E$, where E equals the modulus of elasticity at the maximum metal temperature experienced during the cycle.

(b) Calculate the modified maximum equivalent strain range, $\Delta\epsilon_{\text{mod}}$ using the procedure specified in any one of (c), (d), or (e).

(c) The modified maximum equivalent strain range, $\Delta\epsilon_{\text{mod}}$ may be calculated as:

$$\Delta\epsilon_{\text{mod}} = \left(\frac{S^*}{\bar{S}} \right) K^2 \Delta\epsilon_{\max} \quad (12)$$

(12)

where (see Fig. T-1432-1)

K

= either the equivalent stress concentration factor, as determined by test or analysis, or, the maximum value of the theoretical elastic stress concentration factor in any direction for the local area under consideration. The equivalent stress concentration factor is defined as the effective (von Mises) primary plus secondary plus peak stress divided by the effective primary plus secondary stress. Note that fatigue strength reduction factors developed from low temperature continuous cycling fatigue tests may not be acceptable for defining K when creep effects are not negligible.

S^*

= the stress indicator determined by entering the stress-strain curve of Fig. T-1432-1 at a strain range of $\Delta\epsilon_{\max}$

$\bar{S}$

= the stress indicator determined by entering the stress-strain curve of Fig. T-1432-1 at a strain range of $K\Delta\epsilon_{\max}$

$\Delta\epsilon_{\max}$

= the maximum equivalent strain range as determined above in (a)

$\Delta\epsilon_{\text{mod}}$

= the modified maximum equivalent strain range that accounts for the effects of local plasticity and creep

FIG. T-1420-2 CREEP-FATIGUE DAMAGE ENVELOPE

FIG. T-1420-2 CREEP-FATIGUE DAMAGE ENVELOPE

FIG. T-1432-1 STRESS-STRAIN RELATIONSHIP

FIG. T-1432-1 STRESS-STRAIN RELATIONSHIP

The composite stress-strain curve used for this analysis is shown in Fig. T-1432-1, and it is constructed by adding the elastic stress-strain curve for the stress range, S_{rH} , to the appropriate time-independent isochronous stress-strain curve (σ', ϵ') from Figs. T-1800. The appropriate curve of Figs. T-1800 corresponds to the maximum metal temperature occurring during the cycle.

O	= origin of the composite isochronous stress-strain curve (Fig. T-1432-1) used in this analysis
O'	= origin of the time-independent isochronous stress-strain curve of Figs. T-1800
S_{rH}	= a relaxation strength defined in T-1324
ϵ'	= strain abscissa of the time-independent isochronous stress-strain curve of Figs. T-1800
σ'	= stress ordinate of the time-independent isochronous stress-strain curve of Figs. T-1800

(d) Equation (12) results in a conservative determination of the modified maximum equivalent strain range, $\Delta\epsilon_{\text{mod}}$ relative to the maximum equivalent strain range, $\Delta\epsilon_{\text{max}}$. A more accurate and less conservative determination of the modified maximum equivalent strain range, $\Delta\epsilon_{\text{mod}}$ may then be obtained by use of Eq. (13):

$$\Delta\epsilon_{\text{mod}} = \frac{K^2 S^* \Delta\epsilon_{\text{max}}}{\Delta\sigma_{\text{mod}}} \quad (13)$$

(13) where (see Fig. T-1432-1) $\Delta\epsilon_{\text{mod}}$, $\Delta\epsilon_{\text{max}}$, K , and S^* are as defined in (c) above, and $\Delta\sigma_{\text{mod}}$ = the range of effective stress that corresponds to the strain range, $\Delta\epsilon_{\text{mod}}$ in the composite stress-strain curve of Fig. T-1432-1. The unknowns of Eq. (13), i.e., $\Delta\sigma_{\text{mod}}$ and $\Delta\epsilon_{\text{mod}}$ can be solved graphically or analytically by curve fitting the appropriate composite stress-strain curve. Note that the appropriate composite stress-strain curve is constructed as described above in (c).

(e) The most conservative estimate of the modified maximum equivalent strain range, $\Delta\epsilon_{\text{mod}}$ may be obtained as:

$$\Delta\epsilon_{\text{mod}} = K_e K \Delta\epsilon_{\text{max}} \quad (14)$$

(14) where $\Delta\epsilon_{\text{mod}}$, K , and $\Delta\epsilon_{\text{max}}$ are defined in (c) above, and

$$\begin{aligned} K_e &= 1 \text{ if } K\Delta\epsilon_{\text{max}} \leq 3\bar{S}_m/E \\ K_e &= K\Delta\epsilon_{\text{max}}E/3\bar{S}_m \text{ for } K\Delta\epsilon_{\text{max}} > 3\bar{S}_m/E \end{aligned}$$

(f) Determine the multiaxial plasticity and Poisson ratio adjustment factor, K_v , defined in Eq. (15):

$$K_v = 1.0 + f(K_v' - 1.0), \text{ but not less than } 1.0 \quad (15)$$

(15)

where

K_v'

= plastic Poisson ratio adjustment factor determined by entering Fig. T-1432-3 at the ratio of $K_e K \Delta \epsilon_{\max} E / 3 \bar{S}_M$ with the terms as defined in Eq. (14)

f

= factor determined by entering Fig. T-1432-2 at the Triaxiality Factor, T.F., for the stress state at each of the two extremes of the stress cycle. The larger magnitude of f shall be used in Eq. (15).

(g) Determine the creep strain increment $\Delta \epsilon_c$ for the stress cycle due to load controlled stresses by using a stress intensity equal to 1.25 times the effective creep stress $\sigma_c = Z \bullet S_y$ as defined in T-1332. The rules of T-1321, T-1331, and T-1332 apply to determining $\Delta \epsilon_c$ except that the stress cycle time, including hold time between transients, shall be used instead of the entire service life. The restriction on Q_R in T-1323 relative to Table T-1323 does not apply to determining $\Delta \epsilon_c$. Enter the isochronous stress-strain curve (Figs. T-1800) for the maximum metal temperature during the stress cycle time-temperature block with the 1.25 σ_c stress held constant throughout each temperature-time block of the stress cycle. The $\Delta \epsilon_c$ equals the sum of the creep strain increment accumulated in one stress cycle time. Alternatively, the creep strain accumulated during the entire service life divided by the number of stress cycles during the entire service life may be used for the creep strain increment $\Delta \epsilon_c$. Based on satisfaction of T-1320 and the T-1431(a) rules, the $\Delta \epsilon_c$ value used need not exceed 1% divided by the total number of stress cycles:

$$\sum_{j=1}^P (n)_j$$

(h) The total strain range, ϵ_p , that is used to enter one of the design fatigue curves of Figs. T-1420-1, is calculated as:

$$\epsilon_l = K_v \Delta \epsilon_{\text{mod}} + K \Delta \epsilon_c \quad (16)$$

(16)

where

K

= local geometric concentration factor determined above in

K_v

(c), (d), or (e)

= the multiaxial plasticity and Poisson ratio adjustment factor determined above in (f)

$\Delta\epsilon_c$

= the creep strain increment as determined above in (g)

$\Delta\epsilon_{mod}$

= the modified maximum equivalent strain range as determined above in any one of (c), (d), or (e)

ϵ_t

= the total strain range that is used to enter one of the design fatigue curves of Figs. T-1420-1 to determine the allowable number of cycles, N_d

T-1433 Creep Damage Evaluation

The creep damage term of Eq. (10) is to be evaluated using either the general procedure defined in (a) below or the alternate procedure defined in (b) below. As

Page 129

FIG. T-1432-2 INELASTIC MULTIAXIAL ADJUSTMENTS

FIG. T-1432-2 INELASTIC MULTIAXIAL ADJUSTMENTS

Page 130

noted in (b), the alternate procedure cannot be used for any portion of the service life if the total strain range, ϵ_t [as determined in T-1432(h)], exceeds $3\bar{S}_m/E$ for any of the specified cycle types, j .

FIG. T-1432-3 ADJUSTMENT FOR INELASTIC BIAXIAL POISSON'S RATIO

FIG. T-1432-3 ADJUSTMENT FOR INELASTIC BIAXIAL POISSON'S RATIO

(a) A general procedure for evaluating the creep damage term of Eq. (10) is provided in Steps 1 through 10 below. Steps 3 through 7 are to be repeated for each cycle type j that was evaluated in T-1432. Recall that j extends from 1 to P as defined in T-1411.

Step 1: Considering the entire specified service life, define the total number of hours expended at temperatures above 800°F (700°F for 2 $\frac{1}{4}$ Cr-1Mo) as t_H

Step 2: Define the hold temperature, T_{HT} , to be equal to the local metal temperature that occurs during sustained normal operation.

Step 3: For each cycle type j , define the average cycle time, $\bar{t}_j$, as:

$$\bar{t}_j = t_H / n_j$$

where

n_j	= specified number of applied repetitions of cycle type j
t_H	= total number of hours at elevated temperatures (for the entire service life) as defined in Step 1 above
$\bar{t}_j$	= average cycle time for cycle type j

Step 4: Select the time-independent isochronous stress-strain curve from Figs. T-1800 that corresponds to the hold-time

temperature T_{HT} . Enter that stress-strain curve at a strain level equal to the strain range ϵ_p , where ϵ_t is that value calculated in T-1432(h) for cycle type j . Establish the corresponding stress level, S_j . Note that the same isochronous stress-strain curve is used for all cycle types, since T_{HT} is independent of cycle definition.

Step 5: Account for stress relaxation during the average cycle time $\bar{t}_j$. This stress relaxation evaluation is to be performed at a constant temperature equal to T_{HT} . The initial stress is S_j for cycle type j . The stress relaxation history may be determined by:

(1) an adjusted uniaxial relaxation analysis where the multiaxial stress state is accounted for by using the following equation (depicted in Fig. T-1433-1(b)):

$$S_r = S_j - 0.8G (S_j - \bar{S}_r)$$

where

G

= the smallest value of the multiaxiality factor as determined for the stress state at each of the two extremes of the stress cycle. The multiaxiality factor is defined as:

$$\frac{[\sigma_1 - 0.5(\sigma_2 + \sigma_3)]}{[\sigma_1 - 0.3(\sigma_2 + \sigma_3)]}$$

where σ_1 , σ_2 , and σ_3 are principal stresses, exclusive of local geometric stress concentration factors, at the extremes of the stress cycle, and are defined by:

$$|\sigma_1| \geq |\sigma_2| \geq |\sigma_3|$$

Values of G greater than 1.0 shall be taken as 1.0.

S_j

= the initial stress level for cycle type j

 S_r

= relaxed stress level at time t adjusted for the multiaxial stress state

 $\bar{S}_r$

= relaxed stress level at time t based on a uniaxial relaxation model

or

(2) by entering the appropriate isochronous stress-strain curves of Figs. T-1800 at a strain level equal to ϵ_t and determining corresponding stress levels at varying times (see Fig. T-1433-1). The appropriate isochronous stress-strain curves correspond to the temperature T_{HT} . This stress relaxation process shall not be permitted to proceed to a stress level less than S_{LB} . This lower bound stress level, S_{LB} , is defined to be equal to 1.25 times the core stress σ_c [see T-1432(g)] intensity that exists during sustained normal operation. Note that the same value of S_{LB} is used for all cycle types. This stress relaxation procedure results in a stress-time history similar to that illustrated in Fig. T-1433-2.

Step 6: The average cycle time, $\bar{t}_j$, includes the time expended during elevated temperature transient conditions in addition to the time at the sustained normal operating conditions. Define that portion of $\bar{t}_j$ that represents time expended during elevated temperature transient conditions, as $(t_{TRAN})_j$. Determine the time point, during the transient conditions, for which the load controlled stresses are at maximum conditions. Define $(S_{TRAN})_j$ to be equal to the load controlled stress intensity at that time point. Indicate both $(t_{TRAN})_j$ and $(S_{TRAN})_j$ on the stress-time history (determined in Step 5)

Page 131

FIG. T-1433-1 METHODS OF DETERMINING RELAXATION

FIG. T-1433-1 METHODS OF DETERMINING RELAXATION

Page 132

FIG. T-1433-2 STRESS-RELAXATION LIMITS FOR CREEP DAMAGE

FIG. T-1433-2 STRESS-RELAXATION LIMITS FOR CREEP DAMAGE

above) as shown in Fig. T-1433-3(a). If $(S_{\text{TRAN}})_j$ does not exceed the stress-time history within the time duration $(t_{\text{TRAN}})_j$ [as is illustrated in Fig. T-1433-3(a)], then no further modification of the stress-time history is required. If $(S_{\text{TRAN}})_j$ exceeds the stress-time history within the time duration $(t_{\text{TRAN}})_j$, then the stress-time history must be modified by a simple translation in time, as shown in Fig. T-1433-3(b).

FIG. T-1433-3 STRESS-RELAXATION LIMITS FOR CREEP DAMAGE

FIG. T-1433-3 STRESS-RELAXATION LIMITS FOR CREEP DAMAGE

Step 7: Define the cycle transient temperature, $(T_{\text{TRAN}})_j$, to be equal to the maximum metal temperature that occurs during cycle type j . In no case shall $(T_{\text{TRAN}})_j$ be defined as less than the hold time temperature, T_{HT} . Note that the temperature $(T_{\text{TRAN}})_j$ is not considered in the determination of the stress relaxation history; however, it is considered in the subsequent determination of the creep damage during the time duration $(t_{\text{TRAN}})_j$.

Step 8: The repetition of the above Steps 3 through 7 for $j = 1$ to P will result in P stress/temperature time histories. These stress/temperature time histories are to be superimposed as shown in Fig. T-1433-4.

Step 9: The resulting, composite, stress/temperature time history envelope is divided into q time intervals to facilitate the evaluation of the creep damage term of Eq. (10). These q time intervals are selected to conveniently represent the composite stress/temperature history as a step-wise function of time. During each of these time intervals, $(\Delta t)_k$, the stress, $(S)_k$, and temperature, $(T)_k$, are assumed to be constant and are selected to represent the most damaging stress/temperature combination that could exist during that time interval.

Step 10: For each time interval, $(\Delta t)_k$, the allowable time duration $(T_d)_k$ of Eq. (10) is obtained from the expected minimum stress-to-rupture curve of Figs. I-14.6. The appropriate temperature is $(T)_k$ and the appropriate stress is $(S)_k/K'$, where K' is selected from Table T-1411-1.

(b) Alternatively, the stress/temperature time history can be defined on the basis of a single relaxation cycle for the entire design life. This alternate procedure can be used only if the total strain range ϵ_t [as determined in T-1432(h)] is less than or equal to $3\bar{S}_m/E$ for all specified cycle types, j , considered in T-1432. The

stress-time history for this single relaxation curve is to be constructed using the procedure defined in Steps 1 through 5 in (a) above. For the purposes of this calculation, the average cycle time $\bar{t}_j$ (of Step 5 above) is to be defined as:

FIG. T-1433-4 ENVELOPE STRESS-TIME HISTORY FOR CREEP DAMAGE ASSESSMENT

FIG. T-1433-4 ENVELOPE STRESS-TIME HISTORY FOR CREEP DAMAGE ASSESSMENT

$$\bar{t}_j = t_H$$

where t_H is as defined in Step 1 above. Similarly, the initial stress, S_j (calculated in Step 4 above), is to be based on the maximum value of ϵ_i that was calculated in T-1432(h). The lower bound stress, S_{LB} , is as defined in Step 5 above. The hold-time temperature, T_{HT} , is as defined in Step 2 above. The resulting stress-time history will be similar to that shown in Fig. T-1433-2.

This single cycle, stress-time history is divided into q time intervals to conveniently represent the history as a step-wise function. During each of these time intervals $(\Delta t)_k$ the stress $(S)_k$ is assumed to be constant and is equal to the value at the start of that interval. The temperature $(T)_k$ is constant for the entire design life and is equal to T_{HT} .

For each time interval $(\Delta t)_k$ the allowable time duration $(T_d)_k$ of Eq. (10) is obtained from the expected minimum stress-to-rupture curve of Figs. I-14.6. The appropriate temperature is $(T)_k$ and the appropriate stress is $(S)_k/K'$, where K' is selected from Table T-1411-1.

T-1434 Calculation of Strain Range for Piping

When simplified elastic rules are used for piping analysis utilizing the stress indices of Table NB-3681(a)-1, the equivalent strain range may be calculated directly from Eqs. (12) or (14) by scalar addition of elastic and inelastic strain. The calculation of temperature distributions for use in the simplified analysis must reflect the actual component geometry.

Piping systems shall be assessed for thermal expansion elastic follow-up and its effects shall be accounted for in the strain range ϵ_i and stress intensity S_k assessments of T-1430. The follow-up analysis shall be disclosed and justified in the Design Report.

T-1435 Alternate Creep-Fatigue Evaluation

Providing the limits of T-1324 are satisfied, the rules of T-1431, T-1432, and T-1433 may be replaced by NB-3222.4, except:

Page 134

(a) The reference to Figs. I-9.0 may be replaced by Figs. T-1420-1, where S_a is one half the product of ϵ_t and Young's Modulus E at the metal temperature of the cycle for the point under consideration.

(b) The S_n value in NB-3228.5 and NB-3653.6 shall be taken as S_p .

(c) The cumulative usage factor U shall not exceed 0.90.

(d) Note the exception of T-1412.

T-1500 BUCKLING AND INSTABILITY

T-1510 GENERAL REQUIREMENTS

(a) The stability limits in NB-3133 of Section III pertain only to specific geometrical configurations under specific loading conditions. For example, column mode buckling is not evaluated by NB-3133 and Appendix VII. These Section III limits include the effects of initial geometrical imperfections permitted by fabrication tolerances on vessel shells. However, Section III limits do not consider the effects of creep due to long term loadings at elevated temperatures and the effects of the other loads or other geometries. The T-1500 rules provide additional limits which are applicable to general configurations and loading conditions that may cause buckling or instability due to time-independent as well as time-dependent creep behavior of the material. These additional limits are applicable to all specified Design and Service Loadings.

(b) For the limits specified in T-1520, distinction is made between load controlled buckling and strain-controlled buckling. Load controlled buckling is characterized by continued application of an applied load in the post-buckling regime, leading to failure, e.g., collapse of a tube under external pressure. Strain controlled buckling is characterized by the immediate reduction of strain induced load upon initiation of buckling, and by the self-limiting nature of the resulting deformations. Even though it is self-limiting, strain controlled buckling must be avoided to guard against failure by fatigue, excessive strain, and interaction with load controlled instability.

(c) For conditions under which strain controlled and load controlled buckling may interact, the Load Factors applicable to load controlled buckling shall be used for the combination of load controlled and strain controlled loads to guard against buckling in the interactive mode.

(d) For conditions where significant elastic follow-up may occur, the Load Factors applicable to load controlled buckling shall also be used for strain controlled buckling.

(e) For load controlled buckling, the effects of initial geometrical imperfections and tolerances shall be considered in the time-independent calculations of T-1521; and the effects of the geometrical imperfections and tolerances, whether initially present or induced by service, shall be considered in the time-dependent calculations of T-1522.

(f) For purely strain controlled buckling, the effects of geometrical imperfections and tolerances, whether initially present or induced by service, need not be considered in the calculation of the instability strain. However, if significant geometrical imperfections are present initially, enhancement due to creep may cause excessive deformation or strain. These effects shall be considered in the application of deformation and strain limits of T-1200 and T-1300.

(g) The expected minimum stress-strain curve for the material at the specified temperatures shall be used. The expected minimum values may be obtained by normalizing the inelastic portion of the appropriate average hot tensile curve of Fig. T-1800 to the tabulated yield strength given in Table I-14.5.

When re-solution annealed Type 300 series austenitic stainless steel is utilized, the tabulated yield strength shall be further reduced by 17%. This reduction is not required if it is demonstrated by test that the room temperature yield strength meets the specified minimum values following re-solution annealing.

(h) The limits of both T-1521 and T-1522 shall be satisfied for the specified Design and Service Loadings.

T-1520

T-1520 BUCKLING LIMITS

T-1521 Time-Independent Buckling

For load controlled buckling, the Load Factor, and for strain controlled buckling, the Strain Factor, shall equal or exceed the values given in Table T-1521-1 for the specified Design and Service Loadings to guard against time-independent (instantaneous) buckling. Alternatively, for cylindrical shells under external pressure or axial compression, with or without stiffeners, and for spherical shells under external pressure, the design limits of Section III, Division 1, NB-3133 may be applied.

T-1522 Time-Dependent Buckling

To protect against load controlled time-dependent creep buckling, it shall be demonstrated that instability will not occur during the specified lifetime for a load

Page 135

**TABLE T-1521-1
TIME-INDEPENDENT BUCKLING FACTORS**

	Load Factor [Note (1)]	Strain Factor [Notes (1), (2)]
Design Loadings	3.0	1.67
Service Loadings	3.0	
Level A	3.0	1.67
Level B	3.0	1.67
Level C	2.5	1.4
Level D	1.5	1.1
Test [Note (3)]	2.25	1.67

NOTES:

(1)

$$\text{Load (Strain) Factor} = \left[\begin{array}{c} \text{Load (strain) which would} \\ \text{cause instant instability at} \\ \text{the design (or actual ser-} \\ \text{vice) temperature} \end{array} \right] \div \left[\begin{array}{c} \text{Design or ex-} \\ \text{pected load} \\ \text{(strain)} \end{array} \right]$$

Changes in configuration induced by service need not be considered in calculating the buckling load.

- (2) For thermally induced strain controlled buckling, the Strain Factor is applied to loads induced by thermal strain. To determine the buckling strain, it may be necessary to artificially induce high strains concurrent with the use of realistic stiffness properties. The use of an *adjusted* thermal expansion coefficient is one technique for enhancing the applied strains without affecting the associated stiffness characteristics.
- (3) These factors apply to hydrostatic, pneumatic, and leak tests. Other types of tests shall be classified according to NH-3113.7.

TABLE T-1521-1 TIME-INDEPENDENT BUCKLING FACTORS

history obtained by multiplying the specified Service Loadings by the factors given in Table T-1522-1. A design factor is not required for purely strain controlled buckling because strain controlled loads are reduced concurrently with resistance of the structure to buckling when creep is significant. Alternatively, for temperatures below the limits of Figs. T-1522-1, T-1522-2, or T-1522-3, the design limits of Section III, Division 1, NB-3133 may be applied without consideration of creep effects. The temperature limits of Figs. T-1522-1 and T-1522-2 are given in terms of design life and are applicable for any radius-to-thickness ratio. The temperature limits of Fig. T-1522-3 are given in terms of radius-to-thickness ratio and are applicable for any design life.

TABLE T-1522-1 TIME-DEPENDENT LOAD CONTROLLED BUCKLING FACTORS

T-1700 SPECIAL REQUIREMENTS

T-1710 SPECIAL STRAIN REQUIREMENTS AT WELDS

T-1711 Scope

Because of the potential for limited ductility of weld metal at elevated temperatures and the potential for high strain concentrations (both metallurgical and geometric) in the heat affected zone of weldments, the additional analysis requirements of this Subarticle shall be satisfied for all pressure boundary and other primary structural welds subjected under Service Levels A, B, and C Loadings to metal temperatures where creep effects are significant (see NH-3211). The potential for reduced ductility often precludes locating welds in regions of high loading.

T-1712 Material Properties

In calculating strain deformations in a weld region, the parent material properties shall be used up to the centerline of the weld.

T-1713 Strain Limits

Inelastic strains accumulated in the weld region shall not exceed one-half the strain values permitted for the parent material.

T-1714 Analysis of Geometry

The analysis for strains and creep-fatigue interactions at welds shall use stress and strain concentration factors appropriate for the worst surface geometry and shall be included in the Stress Report (NCA-3350). The worst surface geometry for a given weld shall be determined by the methods described in NH-3353.

T-1715 Creep-Fatigue Reduction Factors

In the vicinity of a weld (defined by ± 3 times the thickness to either side of the weld center line), the creep-fatigue evaluation of T-1400 shall utilize reduced values of the allowable number of design cycles N_d and the allowable time duration T_d in Eq. (10). The N_d value shall be one-half the value permitted for the parent material (Figs. T-1420-1). The T_d value shall

Page 136

Page 137

FIG. T-1522-1 TIME-TEMPERATURE LIMITS FOR APPLICATION OF SECTION II EXTERNAL PRESSURE CHARTS

FIG. T-1522-2 TIME-TEMPERATURE LIMITS FOR APPLICATION OF SECTION II EXTERNAL PRESSURE CHARTS

FIG. T-1522-2 TIME-TEMPERATURE LIMITS FOR APPLICATION OF SECTION II EXTERNAL PRESSURE CHARTS

be determined from a stress-to-rupture curve obtained by multiplying the parent material stress-to-rupture values (Tables I-14.6) by the weld strength reduction factors given in Table I-14.10, and defined in NH-3220. The factor K' (Table T-1411-1) must still be applied in this determination of T_d

FIG. T-1522-3 TEMPERATURE LIMITS FOR APPLICATION OF SECTION II EXTERNAL PRESSURE CHARTS

T-1720 STRAIN REQUIREMENTS FOR BOLTING

T-1721 Strain Limits

The limits of T-1300 shall apply.

T-1722 Creep-Fatigue Damage Accumulation

The fatigue analysis exemptions in NB-3222.4(d) of Section III shall not apply. Creep and fatigue damage shall be assessed using Eq. (10) of T-1411. The total damage factor, D , shall be set at the appropriate value determined from Fig. T-1420-2. Additional requirements are given in (a) and (b) below.

(a) Unless it can be shown by analysis or tests that a lower fatigue strength reduction factor and/or a lower stress rupture reduction factor is appropriate, the reduction factors shall not be less than 4.0 and 1.8, respectively, for the threaded region.

(b) The geometrical restriction of the thread and fillet radii at the end of the shank as described in NB-3232.3(b)(2) and (3) shall apply.

D. 2 $\frac{1}{4}$ Cr-1Mo	1,200	50

TABLE T-1820-1

T-1800 ISOCHRONOUS STRESS-STRAIN RELATIONS

T-1810 OBJECTIVE

This Subarticle provides graphs giving isochronous stress-strain curves, each graph being for a specific material at a specific temperature. The graphs are intended to provide the designer with information regarding the total strain caused by stress under elevated temperature conditions, assuming average material properties.

T-1820 MATERIALS AND TEMPERATURE LIMITS

Table T-1820-1 gives the alloys and temperatures covered by the isochronous stress-strain curves of this Subarticle.

APPENDIX X GUIDELINES FOR RESTRICTED MATERIAL SPECIFICATIONS TO IMPROVE PERFORMANCE IN CERTAIN SERVICE APPLICATIONS

Page 193

X-1100 SCOPE

This Appendix provides guidelines on specification restrictions for Types 304 and 316 stainless steels which will, in the opinion of the Committee, improve the performance of the permitted materials in certain elevated temperature nuclear applications where creep effects are significant. The restrictions have the effect of narrowing chemical composition, grain size, and other aspects of material quality while staying within the broader specification limits defined in Table I-14.1(a) and its notes.

X-1110 OBJECTIVES

The purpose of these restrictions is to achieve materials which have significantly reduced scatter in creep and rupture properties, with mean strength values consistent with or better than the current database, while maintaining satisfactory weldability and fabricability.

X-1200 SERVICE CONDITIONS

The restrictions of this Appendix will provide improved performance when materials are used within the temperature regimes of 800°F to 1,100°F (427°C to 593°C). For application outside of those regimes, this Appendix provides no guidance.

X-1300 RECOMMENDED RESTRICTIONS

The recommended restrictions are shown in Table X-1.

Page 194

**TABLE X-1
RECOMMENDED RESTRICTIONS**

Element	Type 304	Type 316
(a) Chemical Composition [Note (1)]		
Carbon	0.04–0.06	0.04–0.06
Nitrogen	0.04–0.07	0.04–0.07
Silicon	0.6	0.6
Manganese	1.0–2.0	1.0–2.0
Nickel	8.00–10.00	11.00–12.5
Chromium	18.5–20.00	17.00–18.00
Molybdenum	0.2	2.5–3.0
Sulfur	0.02	<0.02
Phosphorus	0.045	<0.03
Niobium	0.02 [Note (2)]	...
Aluminum	0.05	0.05
Antimony	0.02	0.02
Boron	...	0.003 [Note (3)]
Lead	0.003	0.003
Selenium	0.015	0.015
Tin	0.015	0.015
Vanadium	0.05	0.05
Zinc	0.01	0.01
(b) Grain Size (ASTM)	3–6	3–6
(c) Melt Practice	AOD or AOD/ESR	AOD or AOD/ESR
(d) Suggested upper long-term use limit for improved performance:		
Temperature, °F	1,100	1,100

NOTES:

- (1) All values are maximum percentages unless indicated as ranges.
- (2) To further reduce data scatter, a minimum value of 0.005% should be specified.
- (3) To further reduce data scatter, a minimum value of 0.0015% should be specified.

IMPORTANT INFORMATION
ON THE 1998 BOILER AND
PRESSURE VESSEL CODE ADDENDA
DISTRIBUTION SCHEDULE

There is a change in the way the Addenda to the 1998 Edition of the ASME Boiler and Pressure Vessel Code are distributed. The 1998 Edition, published July 1, 1998, incorporates the 1998 Addenda revisions, additions, or deletions. There will be no separate 1998 Addenda issued in a replacement page format. Two additional Addenda to the 1998 Edition, in the form of replacement pages, will be issued on July 1, 1999 and July 1, 2000.

The Summary of Changes published with the 1998 Edition lists and describes the revisions that are part of the 1998 Addenda. These changes are identified with a margin note, **98**, denoting the affected area.

The Addenda for 1999 and 2000 will also have a Summary of Changes and identifiers printed on the replacement pages. The revisions, additions, or deletions will be incorporated directly into the affected pages. It is advisable to retain the title sheets and all replaced pages for reference.

The effective dates for Code Editions and Addenda are described in the Foreword.

Date of Issue - July 1, 1998
(Includes all Addenda dated December 1997 and earlier)

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items

mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

The footnotes in this document are part of this American National Standard.

ADDENDA

Colored-sheet Addenda, which include additions and revisions to individual Sections of the Code, are published annually and will be sent automatically to purchasers of the applicable Sections up to the publication of the 2001 Code. The 1998 Code is available only in the loose-leaf format; accordingly, the Addenda will be issued in the loose-leaf, replacement-page format.

INTERPRETATIONS

ASME issues written replies to inquiries concerning interpretation of technical aspects of the Code. The Interpretations for each individual Section will be published separately and will be included as part of the update service to that Section. They will be issued semiannually (July and December) up to the publication of the 2001 Code. Interpretations of Section III, Divisions 1 and 2, will be included with the update service to Subsection NCA.

CODE CASES

The Boiler and Pressure Vessel Committee meets regularly to consider proposed additions and revisions to the Code and to formulate Cases to clarify the intent of existing requirements or provide, when the need is urgent, rules for materials or constructions not covered by existing Code rules. Those Cases which have been adopted will appear in the appropriate 1998 Code Cases book: (1) Boilers and Pressure Vessels and (2) Nuclear Components. Supplements will be sent automatically to the purchasers of the Code Cases books up to the publication of the 2001 Code.

Page v

FOREWORD

The American Society of Mechanical Engineers set up a committee in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. This committee is now called the Boiler and Pressure Vessel Committee.

The Committee's function is to establish rules of safety governing the design, fabrication, and inspection during construction of boilers and pressure vessels, and to interpret these rules when questions arise regarding their intent. In formulating the rules, the Committee considers the needs of users, manufacturers, and inspectors of pressure vessels. The objective of the rules is to afford reasonably certain protection of life and property and to provide a margin for deterioration in service so as to give a reasonably long, safe period of usefulness. Advancements in design and material and the evidence of experience have been recognized.

This Code contains mandatory requirements, specific prohibitions, and nonmandatory guidance for construction,¹ and inservice inspection and testing activities. The Code does not address all aspects of these activities and those aspects which are not specifically addressed should not be considered prohibited. The Code is not a handbook and cannot replace education, experience, and the use of engineering judgment. The phrase *engineering judgment* refers to technical judgments made by knowledgeable engineers experienced in the application of the Code. Engineering judgments must be consistent with Code philosophy and such judgments must never be used to overrule mandatory requirements or specific prohibitions of the Code.

¹ Construction, as used in this Foreword, is an all-inclusive term comprising materials, design, fabrication, examination, inspection, testing, certification, and pressure relief.

The Committee recognizes that tools and techniques used for design and analysis change as technology progresses and expects engineers to use good judgment in the application of these tools. The designer is responsible for complying with Code rules and demonstrating compliance with Code equations when such equations are mandatory. The Code neither requires nor prohibits the use of computers for the design or analysis of components constructed to the requirements of the Code. However, designers and engineers using computer programs for design or analysis are cautioned that they are responsible for all technical assumptions inherent in the programs they use and they are responsible for the application of these programs to their design.

The Code does not fully address tolerances. When dimensions, sizes, or other parameters are not specified with tolerances, the values of these parameters are considered nominal and allowable tolerances or local variances may be considered acceptable when based on engineering judgment and standard practice as determined by the engineer.

The Boiler and Pressure Vessel Committee deals with the care and inspection of boilers and pressure vessels in service only to the extent of providing suggested rules of good practice as an aid to owners and their inspectors.

The rules established by the Committee are not to be interpreted as approving, recommending, or endorsing any proprietary or specific design or as limiting in any way the manufacturer's freedom to choose any method of design or any form of construction that conforms to the Code rules.

The Boiler and Pressure Vessel Committee meets regularly to consider revisions of the rules, new rules as dictated by technological development, Code Cases, and requests for interpretations. Only the Boiler and Pressure Vessel Committee has the authority to provide official interpretations of this Code. Requests for revisions, new rules, Code Cases, or interpretations shall be addressed to the Secretary in writing and shall give full particulars in order to receive consideration and action (see Mandatory Appendix covering preparation of technical inquiries). Proposed revisions to the Code resulting from inquiries will be presented to the Main Committee for appropriate action. The action of the Main Committee becomes effective only after confirmation by letter ballot of the Committee and approval by ASME.

Proposed revisions to the Code approved by the Committee are submitted to the American National Standards Institute and published in *Mechanical Engineering*

Page viii

to invite comments from all interested persons. After the allotted time for public review and final approval by ASME, revisions are published annually in Addenda to the Code.

Code Cases may be used in the construction of components to be stamped with the ASME Code symbol beginning with the date of their approval by ASME.

Code Editions may be used on or after the date of issue shown in the Edition. After Code revisions are approved by ASME, they may be used beginning with the date of issue shown on the Addenda. Revisions to material specifications are originated by the American Society for Testing and Materials (ASTM) and other recognized national or international organizations, and are usually adopted by ASME. However, those revisions may or may not have any effect on the suitability of material, produced to earlier editions of specifications, for use in ASME construction. ASME material specifications approved for use in each construction Code are listed in the Appendices of Section II, Parts A and B. These Appendices list, for each specification, the latest edition adopted by ASME, and earlier and later editions considered by ASME to be identical for ASME construction.

Owners of nuclear power plants are cautioned that Code Editions, Addenda, and Cases to be used in construction shall be acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

Each state and municipality in the United States and each province in Canada that adopts or accepts one or more Sections of the Boiler and Pressure Vessel Code is invited to appoint a representative to act on the Conference Committee to the Boiler and Pressure Vessel Committee. Since the members of the Conference Committee are in active contact with the administration and enforcement of the rules, the requirements for inspection in this Code correspond with those in effect in their respective jurisdictions. The required qualifications for an Authorized Inspector under these rules may be obtained from the administrative authority of any state, municipality, or province which has adopted these rules.

The Boiler and Pressure Vessel Committee in the formulation of its rules and in the establishment of maximum design and operating pressures considers materials, construction, method of fabrication, inspection, and safety devices. Permission may be granted to regulatory bodies and organizations publishing safety standards to use a complete Section of the Code by reference. If usage of a Section, such as Section IX, involves exceptions, omissions, or changes in provisions, the intent of the Code might not be attained.

Where a state or other regulatory body, in the printing of any Section of the Boiler and Pressure Vessel Code, makes additions or omissions, it is recommended that such changes be clearly indicated.

The National Board of Boiler and Pressure Vessel Inspectors is composed of chief inspectors of states and municipalities in the United States and of provinces in Canada that have adopted the Boiler and Pressure Vessel Code. This Board, since its organization in 1919, has functioned to uniformly administer and enforce the rules of the Boiler and Pressure Vessel Code. The cooperation of that organization with the Boiler and Pressure Vessel Committee has been extremely helpful.

The Code Committee does not rule on whether a component shall or shall not be constructed to the provisions of the Code. The Scope of each Section has been established to identify the components and parameters considered by the Committee in formulating the Code rules. Laws or regulations issued by municipality, state, provincial, federal, or other enforcement or regulatory bodies having jurisdiction at the location of an installation establish the mandatory applicability of the Code rules, in whole or in part, within their jurisdiction. Those laws or regulations may require the use of this Code for vessels or components not considered to be within its Scope or may establish additions or deletions in that Scope. Accordingly, inquiries regarding such laws or regulations are to be directed to the issuing enforcement or regulatory body.

Questions or issues regarding compliance of a specific component with the Code rules are to be directed to the ASME Certificate Holder (Manufacturer). Inquiries concerning the interpretation of the Code are to be directed to the ASME Boiler and Pressure Vessel Committee. ASME is to be notified should questions arise concerning improper use of an ASME Code symbol.

The specifications for materials given in Section II are identical with or similar to those of specifications published by ASTM, AWS, and other recognized national or international organizations. When reference is made in an ASME material specification to a non- ASME specification for which a companion ASME specification exists, the reference shall be interpreted as applying to the ASME material specification. Not all materials included in the material specifications in Section II have been adopted for use in this Section. Usage is limited to those materials and grades listed in at least one of the tables of Section II, Part D, Subpart 1, identified as applicable to this Section. All materials allowed by this Section and used for construction within the scope of these rules shall be furnished in accordance with material specifications

Page ix

contained in Section II or referenced in Appendices A of Section II, Parts A and B except where otherwise provided in Code Cases or in this Section of the Code. Materials covered by these specifications are acceptable for use in items covered by the Code Sections only to the degree indicated in the applicable Section. Materials for Code use should preferably be ordered, produced, and documented on this basis. Material produced to an acceptable specification with requirements different from the requirements of the corresponding specification listed in Appendix A of Part A or Part B may also be used in accordance with the above, provided the material manufacturer or vessel manufacturer certifies with evidence acceptable to the Authorized Inspector that the corresponding ASME specification requirements of specifications listed in Appendix A of Part A or Part B have been met. Material produced to an acceptable material specification is not limited as to country of origin.

When required by context in this Section, the singular shall be interpreted as the plural, and vice-versa; and the feminine, masculine, or neuter gender shall be treated as such other gender as appropriate.

Publication of the SI (Metric) Edition of the ASME Boiler and Pressure Vessel Code was discontinued with the 1986 Edition. Effective October 1, 1986, the SI Edition was withdrawn as an ASME Boiler and Pressure Vessel Code document.

Page xi

STATEMENT OF POLICY ON THE USE OF CODE SYMBOLS AND CODE AUTHORIZATION IN ADVERTISING

ASME has established procedures to authorize qualified organizations to perform various activities in accordance with the requirements of the ASME Boiler and Pressure Vessel Code. It is the aim of the Society to provide recognition of organizations so authorized. An organization holding authorization to perform various activities in accordance with the requirements of the Code may state this capability in its advertising literature.

Organizations that are authorized to use Code Symbols for marking items or constructions which have been constructed and inspected in compliance with the ASME Boiler and Pressure Vessel Code are issued Certificates of Authorization. It is the aim of the Society to maintain the standing of the Code Symbols for the benefit of the users, the enforcement jurisdictions, and the holders of the symbols who comply with all requirements.

Based on these objectives, the following policy has been established on the usage in advertising of facsimiles of the symbols, Certificates of Authorization, and reference to Code construction. The American Society of Mechanical Engineers does not "approve," "certify," "rate," or "endorse" any item, construction, or activity and there shall be no statements or implications which might so indicate. An organization holding a Code Symbol and/or a Certificate of Authorization may state in advertising literature that items, constructions, or activities "are built (produced or performed) or activities conducted in accordance with the requirements of the ASME Boiler and Pressure Vessel Code," or "meet the requirements of the ASME Boiler and Pressure Vessel Code."

The ASME Symbol shall be used only for stamping and nameplates as specifically provided in the Code. However, facsimiles may be used for the purpose of fostering the use of such construction. Such usage may be by an association or a society, or by a holder of a Code Symbol who may also use the facsimile in advertising to show that clearly specified items will carry the symbol. General usage is permitted only when all of a manufacturer's items are constructed under the rules.

The ASME logo, which is the cloverleaf with the letters ASME within, shall not be used by any organization other than

ASME.

STATEMENT OF POLICY ON THE USE OF ASME MARKING TO IDENTIFY MANUFACTURED ITEMS

The ASME Boiler and Pressure Vessel Code provides rules for the construction of boilers, pressure vessels, and nuclear components. This includes requirements for materials, design, fabrication, examination, inspection, and stamping. Items constructed in accordance with all of the applicable rules of the Code are identified with the official Code Symbol Stamp described in the governing Section of the Code.

Markings such as "ASME," "ASME Standard," or any other marking including "ASME" or the various Code Symbols shall not be used on any item which is not constructed in accordance with all of the applicable requirements of the Code.

Items shall not be described on ASME Data Report Forms nor on similar forms referring to ASME which tend to imply that all Code requirements have been met when, in fact, they have not been. Data Report Forms covering items not fully complying with ASME requirements should not refer to ASME or they should clearly identify all exceptions to the ASME requirements.

W. E. Somers
L. P. Zick, Jr.

HONORS AND AWARDS COMMITTEE

J. R. MacKay, *Chair*
A. J. Spencer, *Vice Chair*
F. R. Lyons, *Secretary*
F. P. Barton
W. J. Carter
J. G. Feldstein
M. Gold

F. E. Gregor
E. C. Kistner, Jr.
T. P. Pastor
R. F. Reedy

MARINE CONFERENCE GROUP

J. Tiratto, *Chair*
C. F. Banks
L. W. Douthwaite
J. L. Jones
G. F. Wright

CONFERENCE COMMITTEE

D. E. Tanner - Tennessee (*Chair*)
R. D. Reetz - North Dakota (*Vice Chair*)
A. J. Justin - National Board of Boiler and Pressure Vessel Inspectors (*Secretary*)
R. J. Aben, Jr. - Michigan
J. S. Aclaro - Los Angeles, California
E. A. Anderson - Chicago, Illinois
J. Anderson - South Dakota
R. Barkdoll - Washington
F. P. Barton - Virginia
C. Castle - Nova Scotia, Canada
R. R. Cate - Louisiana
L. Chase - Northwest Territories, Canada
R. A. Coomes - Kentucky
J. Corcoran - Connecticut
M. H. Diehl, Jr. - Maryland
D. A. Douin - Illinois
D. Eastman - Newfoundland and Labrador, Canada
G. L. Ebeyer - New Orleans, Louisiana
F. Ellis - New Hampshire
E. Everett - Georgia
P. C. Hackford - Utah
D. Hanrath - North Carolina
J. B. Harlan - Delaware
K. Hynes - Prince Edward Island, Canada
D. T. Jagger - Ohio
D. J. Jenkins - Kansas
M. Kotb - Quebec, Canada
J. P. Larson - Minnesota
K. T. Lau - Alberta, Canada
J. Lemire - California
G. A. Lundberg - Florida
W. C. Lundine - Oregon
M. A. Malek - Maine
I. W. Mault - Manitoba, Canada
H. T. McEwen - Mississippi

H. T. McEwen - Mississippi
A. W. Meiring - Indiana
R. Mile - Ontario, Canada
T. J. Monroe - Oklahoma
Y. Nagpaul - Hawaii
J. D. Payton - Pennsylvania
D. K. Peetz - Missouri
D. C. Price - Yukon Territory, Canada
R. S. Pucek - Wisconsin
T. E. Rennie - Arizona
L. Roussinos - British Columbia, Canada
M. Shuff - West Virginia
R. Snyder - New Jersey
N. Surtees - Saskatchewan, Canada
M. J. Verhagen - Wisconsin
R. B. West - Iowa
M. J. Wheel - Vermont
K. A. White - Nevada
R. K. White - New York
T. F. Wickham - Rhode Island
C. S. Withers - Colorado

SUBCOMMITTEE ON POWER BOILERS (SC I)

J. R. MacKay, *Chair*
M. D. Bernstein, *Vice Chair*
P. D. Stumpf, *Secretary*
D. L. Berger
E. Everett
D. N. French
F. R. Gerety
J. Hainsworth
T. E. Hansen
J. S. Hunter
W. L. Lowry
T. C. McGough
P. A. Molvie
D. K. Parrish
J. T. Pillow
R. G. Presnak
B. W. Roberts
R. D. Schueler, Jr.
R. V. Wielgoszinski
R. L. Williams

ORGANIZATION OF SECTION III

1. GENERAL

Section III consists of Division 1, Division 2, and Division 3. These Divisions are broken down into Subsections and are designated by capital letters preceded by the letter "N" for Division 1, by the letter "C" for Division 2, and by the letter "W" for Division 3. The following eleven books make up the three Divisions.

Subsection NCA - General Requirements for Division 1 and Division 2

Division 1

Subsection NB - Class 1 Components

Subsection NC - Class 2 Components

Subsection ND - Class 3 Components

Subsection NE - Class MC Components

Subsection NF - Supports

Subsection NG - Core Support Structures

Subsection NH - Class 1 Components in Elevated Temperature Service

Appendices

Division 2 - Code for Concrete Reactor Vessels and Containments

Division 3 - Containment Systems and Transport Packagings for Spent Nuclear Fuel and High Level Radioactive Waste

The Division 2 book includes Subsection CC - Concrete Containments and Division 2 Appendices.

The Division 3 book includes Subsections WA and WB for General Requirements and Class TP (Type B) Containment, respectively.

2. SUBSECTIONS

Subsections are divided into Articles, Subarticles, paragraphs, and, where necessary, subparagraphs and subsubparagraphs.

3. ARTICLES

Articles are designated by the applicable letters indicated above for the Subsections followed by Arabic numbers, such as NB-1000. Where possible, Articles dealing with the same topics are given the same number in each Subsection in accordance with the following general scheme:

Article Number	Title
1000	Introduction or Scope
2000	Material
3000	Design
4000	Fabrication and Installation
5000	Examination

6000	Examination
7000	Testing
8000	Overpressure Protection
	Nameplates, Stamping, and Reports

The numbering of Articles and the material contained in the Articles may not, however, be consecutive. Due to the fact that the complete outline may cover phases not applicable to a particular Subsection or Article, the rules have been prepared with some gaps in the numbering.

4. SUBARTICLES

Subarticles are numbered in units of 100, such as NB-1100.

5. SUBSUBARTICLES

Subsubarticles are numbered in units of 10, such as NB-2130, and generally have no text. When a number such as NB-1110 is followed by text, it is considered a paragraph.

6. PARAGRAPHS

Paragraphs are numbered in units of 1, such as NB-2121.

7. SUBPARAGRAPHS

Subparagraphs, when they are *major* subdivisions of a paragraph, are designated by adding a decimal followed by one or more digits to the paragraph number, such as NB-1132.1. When they are *minor* subdivisions of a paragraph, subparagraphs may be designated by lowercase letters in parentheses, such as NB-2121(a).

8. SUBSUBPARAGRAPHS

Subsubparagraphs are designated by adding lowercase letters in parentheses to the *major* subparagraph numbers, such as NB-1132.1(a). When further subdivisions of *minor* subparagraphs are necessary, subsubparagraphs are designated by adding Arabic numerals in parentheses to the subparagraph designation, such as NB-2121(a)(1).

Page xxiv

9. REFERENCES

References used within Section III generally fall into one of the following four categories.

A. References to Other Portions of Section III

When a reference is made to another Article, Subarticle, or paragraph, all numbers subsidiary to that reference shall be included. For example, reference to NB-3000 includes all material in Article NB-3000; reference to NB-3200 includes all material in Subarticle NB-3200; reference to NB-3230 includes all paragraphs NB-3231 through NB-3236.

B. References to Other Sections

Other Sections referred to in Section III are:

Section II, Materials. When a requirement for a material, or for the examination or testing of a material, is to be in accordance with a specification such as SA-105, SA-370, or SB-160, the reference is to material specifications in Section II. These references begin with the letter "S."

Section V, Nondestructive Examination. Section V references begin with the letter "T" and relate to the nondestructive examination of material or welds.

Section IX, Welding and Brazing Qualifications. Section IX references begin with the letter "Q" and relate to welding and brazing requirements.

Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components. When a reference is made to inservice

inspection, the rules of Section XI shall apply.

C. Reference to Specifications and Standards Other Than Published in Code Sections

(1) Specifications for examination methods and acceptance standards to be used in connection with them are published by the American Society for Testing and Materials. At the time of publication of Section III, some such specifications were not included in Section II of this Code. A reference to ASTM E 71-64 refers to the specification so designated by and published by ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

2 The American National Standards Institute (ANSI) was formerly known as the American Standards Association. Standards approved by the Association were designated by the prefix "ASA" followed by the number of the standard and the year of publication. More recently, the American National Standards Institute was known as the United States of America Standards Institute. Standards were designated by the prefix "USAS" followed by the number of the standard and the year of publication. While the letters of the prefix have changed with the name of the organization, the numbers of the standards have remained unchanged.

(2) Dimensional standards covering products such as valves, flanges, and fittings are sponsored and published by the American Society of Mechanical Engineers and approved by the American National Standards Institute.² When a product is to conform to such a standard, for example ANSI B16.5, the standard is approved by the American National Standards Institute. The applicable year of issue is that suffixed to its numerical designation in Table NB-3132-1, for example ANSI B16.5-1977. Standards published by the American Society of Mechanical Engineers are available from ASME, 22 Law Drive, Box 2300, Fairfield, NJ 07007-2300.

(3) Dimensional and other types of standards covering products such as valves, flanges, and fittings are also published by the Manufacturers Standardization Society of the Valve and Fittings Industry and are known as Standard Practices. When a product is required by these rules to conform to a Standard Practice, for example MSS SP-6, the Standard Practice referred to is published by the Manufacturers Standardization Society of the Valve and Fittings Industry, 127 Park Street, N.E., Vienna, VA 22180. The applicable year of issue of such a Standard Practice is that suffixed to its numerical designation in Table NB-3132-1, for example MSS SP-6-1963.

(4) Specifications for welding and brazing materials are published by the American Welding Society, 550 N.W. LeJeune Road, Miami, FL 33135. Specifications of this type are incorporated in Section II and are identified by the AWS designation with the prefix "SF," for example SFA-5.1.

(5) Standards applicable to the design and construction of tanks and flanges are published by the American Petroleum Institute and have designations such as API-620 and API-2000. When documents so designated are referred to in Section III, they are standards published by the American Petroleum Institute.

D. References to Appendices

Two types of Appendices are used in Section III and are designated Mandatory and Nonmandatory.

(1) Mandatory Appendices contain requirements which must be followed in construction; such references are designated by a Roman numeral followed by Arabic numerals. References to II-1100 or XI-3212, for example, relate to the Mandatory Appendices.

(2) Nonmandatory Appendices provide information or guidance for the use of Section III; such references are designated by a capital letter followed by Arabic numerals. A reference to D-1100, for example, relates to a Nonmandatory Appendix.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 APP SI UNITS

SI UNITS

The 1998 Edition of the Boiler and Pressure Vessel Code is based on U.S. Customary (ft-lb) units of measurement which are to be regarded as the standard. This supplement is provided as a convenience to the Code user and contains SI conversion factors for units contained in the Code.

LIST OF SI UNITS FOR USE WITH ASME BOILER AND PRESSURE VESSEL CODE¹

Quantity	Unit	Symbol	Other Units or Limitations
Space and Time			
plane angle	radian	rad	degree (decimalized)
length	meter	m	
area	square meter	m ²	
volume	cubic meter	m ³	liter (L) for liquid only (use without prefix other than in milliliter, mL)
time	second	s	minute (min), hour (h), day (d), week, and year
Periodic and Related Phenomena			
frequency	hertz	Hz	revolutions per second (r/s)
rotational frequency	revolutions per second	s ⁻¹	revolutions per minute (r/m)
Mechanics			
mass	kilogram	kg	
density	kilogram per cubic meter	kg/m ³	
moment of inertia	kilogram · meter ²	kg · m ²	
force	newton	N	
moment of force (torque)	newton-meter	N · m	
pressure and stress	pascal	Pa	(pascal = newton per square meter)
energy, work	joule	J	kilowatt-hour (kW · h)
power	watt	W	
impact strength	joule	J	
section modulus	meter ³	m ³	
moment of section (second moment of area)	meter ⁴	m ⁴	
fracture toughness	Pa · $\sqrt{m}$		
Heat			
temperature — thermodynamic [Note (2)]	kelvin	K	degree Celsius (°C)
temperature — other than thermodynamic	degree Celsius	°C	kelvin (K)
linear expansion coefficient	meter per meter-kelvin	K ⁻¹	°C ⁻¹
quantity of heat	joule	J	
heat flow rate	watt	W	
thermal conductivity	watt per meter-kelvin	W/(m · K)	W/(m · °C)
thermal diffusivity	square meter per second	m ² /s	
specific heat capacity	joule per kilogram-kelvin	J/(kg · K)	J/(kg · °C)
Electricity and Magnetism			
electric current	ampere	A	
electric potential	volt	V	
current density	ampere per meter ²	A/m ²	
magnetic field strength	ampere per meter	A/m	

NOTES:

- (1) Conversion factors between SI units and U.S. customary are given in SI-1, "ASME Orientation and Guide for Use of SI (Metric) Units," and ASTM E 380.
- (2) Preferred use for temperature and temperature interval is degrees Celsius (°C), except for thermodynamic and cryogenic work where kelvins may be more suitable. For temperature interval, 1 K = 1°C exactly.

LIST OF SI UNITS FOR USE WITH ASME BOILER AND PRESSURE VESSEL CODE¹

COMMONLY USED CONVERSION FACTORS (For Others See ASTM E 380) [See Note (1)]

Quantity	To Convert From	To	Multiply by [Note (2)]	
plane angle	degree	rad	1.745 329	E-02
length	in	m	2.54*	E-02
	ft	m	3.048*	E-01
	yd	m	9.144*	E-01
area	in ²	m ²	6.451 6*	E-04

	lbf/in ² (psi)	Pa	6.894 757	E+03
	kips/in ²	Pa	6.894 757	E+06
	bar	Pa	1.0*	E+05
energy, work	Btu (IT) [Note (3)]	J	1.055 056	E+03
	ft · lbf	J	1.355 818	E+00
power	hp (550 ft · lbf/s)	W	7.456 999	E+02
fracture toughness	ksi $\sqrt{\text{in}}$	Pa · $\sqrt{\text{m}}$	1.098 843	E+06
temperature	°C	K	$t_K = t_C + 273.15$	
	°F	K	$t_K = (t_F + 459.67)/1.8$	
	°F	°C	$t_C = (t_F - 32)/1.8$	
temperature interval	°C	K	1.0*	E+00
	°F	K or °C	5.555 555	E-01

NOTES:

(1) Care should be taken when converting formulas or equations that contain constant terms or factors. The value of these terms must be understood and may also require conversion.

(2)(a) Relationships that are exact in terms of the base units are followed by a single asterisk.

(b) The factors are written as a number greater than 1 and less than 10 with 6 or less decimal places. The number is followed by the letter E (for exponent), a plus or minus symbol, and two digits which indicate the power of 10 by which the number must be multiplied to obtain the correct value. For example: 3.523 907 E-02 is $3.523\ 907 \times 10^{-2}$ or 0.035 239 07.

NOTES:
(1) These data points are included to provide accurate representation of curves at branches or cusps.
(2) Interpolation between tabular values is permissible based upon data representation by straight lines on a log-log plot. Accordingly, for $S_a > S_y$.

(3) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(4) These data points are included to provide accurate representation of curves at branches or cusps.

(5) MIS is the Minimum Tensile Stress.

(6) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(7) MIS is the Minimum Tensile Stress.

(8) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(9) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(10) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(11) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(12) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(13) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(14) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(15) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(16) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(17) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(18) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(19) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

(20) The number of cycles indicated shall be read as follows: 1E1 = 1×10^1 cycles, 2E2 = 2×10^2 or 200 cycles, etc.

FIG. 1-9.1 DESIGN FATIGUE CURVES FOR CARBON, LOW ALLOY, AND HIGH TENSILE STEELS FOR METAL TEMPERATURES NOT EXCEEDING 700°F

TEMPERATURES NOT EXCEEDING 700 F

FIG. I-9.1 DESIGN FATIGUE CURVES FOR CARBON, LOW ALLOY, AND HIGH TENSILE STEELS FOR METAL TEMPERATURES NOT EXCEEDING 700°F

FIG. I-9.2

FIG. I-9.2.1 DESIGN FATIGUE CURVE FOR AUSTENITIC STEELS, NICKEL-CHROMIUM-IRON ALLOY, NICKEL-IRON-CHROMIUM ALLOY, AND NICKEL-COPPER ALLOY FOR $S_u > 28.2 \text{ ksi}$, FOR TEMPERATURES NOT EXCEEDING 800°F
(For $S_u \leq 28.2 \text{ ksi}$, use Fig. I-9.2.2.)

Table I-9.1 Contains Tabulated Values and a Formula for Accurate Interpolation of This Curve

FIG. I-9.2.1 DESIGN FATIGUE CURVE FOR AUSTENITIC STEELS, NICKEL-CHROMIUM-IRON ALLOY, NICKEL-IRON-CHROMIUM ALLOY, AND NICKEL-COPPER ALLOY FOR $S_a > 28.2$ ksi, FOR TEMPERATURES NOT EXCEEDING 800°F

Criteria for the Use of the Curves in This Figure
 [Notes (1)–(5)]

Curve	Elastic Analysis of Material Other Than Welds and Adjacent Base Metal	Elastic Analysis of Welds and Adjacent Base Metal
A	$(P_L + P_b + Q)_{\text{Range}} \leq 27.2$ ksi	...
B	$(P_L + P_b + Q)_{\text{Range}} > 27.2$ ksi and S_a is corrected for applied mean stress	$(P_L + P_b + Q)_{\text{Range}} \leq 27.2$ ksi
C	$(P_L + P_b + Q)_{\text{Range}} > 27.2$ ksi	$(P_L + P_b + Q)_{\text{Range}} > 27.2$ ksi

- NOTES:
- (1) Range applies to the individual quantities P_L , P_b , and Q and applies to the set of cycles under consideration.
 - (2) Thermal bending stresses resulting from axial and radial gradients are excluded from Q .
 - (3) Curve A is also to be used with inelastic analysis with $S_a = \frac{3}{2} \Delta \epsilon_t E$, where $\Delta \epsilon_t$ is the total effective strain range.
 - (4) The maximum effect of retained mean stress is included in Curve C.
 - (5) The adjacent base metal is defined as three wall thicknesses from the center line of the weld.

FIG. I-9.2.2 DESIGN FATIGUE CURVES FOR AUSTENITIC STEELS, NICKEL-CHROMIUM-IRON ALLOY, NICKEL-IRON-CHROMIUM ALLOY, AND NICKEL-COPPER ALLOY FOR $S_a \leq 28.2$ ksi, FOR TEMPERATURES NOT EXCEEDING 800°F
 (For $S_a > 28.2$ ksi, use Fig. I-9.2.1.)

Table I-9.2.2 Contains Tabulated Values for Accurate Interpolation of This Curve

FIG. I-9.2.2 DESIGN FATIGUE CURVES FOR AUSTENITIC STEELS, NICKEL-CHROMIUM-IRON ALLOY, AND NICKEL-IRON-CHROMIUM ALLOY, AND NICKEL-ALLOY FOR $S_a \leq 28.2$ ksi, FOR TEMPERATURES NOT EXCEEDING 800°F

SEC III D1 MA APP II

APPENDIX II EXPERIMENTAL STRESS ANALYSIS

Page 25

ARTICLE II-1000 EXPERIMENTAL STRESS ANALYSIS**II-1100 INTRODUCTION****II-1110 GENERAL REQUIREMENTS****II-1111 When Experimental Stress Analysis Is Required**

The critical or governing stresses in parts for which theoretical stress analysis is inadequate or for which design rules are unavailable shall be substantiated by experimental stress analysis.

II-1112 When Reevaluation Is Not Required

Reevaluation is not required for configurations for which there are available detailed experimental results that are

consistent with the requirements of this Article.

II-1113 Discounting of Corrosion Allowances

The test procedures followed and the interpretation of the results shall be such as to discount the effects of material added to the thickness of members, such as corrosion allowance, or of other material which cannot be considered as contributing to the strength of the part.

II-1114 Inspection and Reports

Tests conducted in accordance with this Article need not be witnessed by the Inspector. However, a detailed report of the test procedure and the results obtained shall be included with the Design Report (NCA-3551). The report shall show that the instrumentation used was within calibration.

II-1200 PERMISSIBLE TYPES OF NONCYCLIC TESTS AND CALCULATION OF STRESSES

II-1210 TESTS FOR DETERMINING GOVERNING STRESSES

Permissible types of tests for the determination of governing stresses are strain measurement tests and photoelastic tests. Brittle coating tests may be used only for the purpose described in II-1310.

II-1220 TESTS FOR DETERMINING COLLAPSE LOAD

Strain measurement tests may be used for the determination of collapse load. Distortion measurement tests may be used for the determination of collapse load if it can be clearly shown that the test setup and the instrumentation used will give valid results for the configuration on which the measurements are made.

II-1221 Fatigue Tests for Evaluation of Cyclic Loading

Fatigue tests as described in II-1500 may be used to evaluate the adequacy of a component or portion thereof for cyclic loading.

II-1230 TESTS TO DESTRUCTION

Results of tests to destruction are not acceptable except as provided for piping in NB-3649.

II-1240 CALCULATION OF STRESSES

A modified Poisson's ratio is given by NB-3227.6 and identified as being applicable only to local thermal stresses. It should be noted that some situations can arise in which the use of the modified value of Poisson's

Page 28

ratio is indicated for the calculation of stresses of other than thermal origin. Strictly speaking, this modified value should be used in any calculation which results in stresses which exceed a stress intensity range of $2S_y$. For designs which meet the basic stress limits this modification is important only for local thermal stresses such as skin stresses. When calculating the stress range in an element such as a fatigue test model which does not meet the basic stress limits, the effect of the modified Poisson's ratio should be considered.

II-1250 STRAIN MEASUREMENT TEST PROCEDURE

II-1251 Requirements for Strain Gages

Strain gages of any type capable of indicating strains to 0.00005 in./in. may be used. It is recommended that the gage length be such that the maximum strain within the gage length does not exceed the average strain within the gage length by more than 10%. Instrumentation shall be such that both surface principal stresses may be determined at each gage location in the elastic range of material behavior at that gage location. A similar number and orientation of gages at each gage location are required to be used in tests beyond the elastic range of material behavior. The strain gages and cements

that are used shall be shown to be reliable for use on the material surface finish and configuration considered to strain values at least 50% higher than those expected.

II-1252 Use of Models for Strain or Distortion Measurements

(a) Except in tests made for the measurement of collapse load, strain gage data may be obtained from the actual component or from a model component of any scale that meets the gage length requirements of II-1251. The model material need not be the same as the component material but shall have an elastic modulus which is either known or has been measured at the test conditions. The requirements of dimensional similitude shall be met as nearly as possible.

(b) In the case of collapse load tests, only full scale models, prototypical in all respects, are permitted unless the experimenter can clearly demonstrate the validity of the scaling laws used.

II-1260 PHOTOELASTIC TEST TECHNIQUES

Either two dimensional or three dimensional techniques may be used in photoelastic testing as long as the model represents the structural effects of the loading.

II-1300 TEST PROCEDURES

II-1310 LOCATION OF TEST GAGES

(a) In tests for determination of governing stresses, sufficient locations on the component shall be investigated to ensure that the measurements are taken at the most critical areas and to permit conservative determination of the bending and peak stress components. The location of the critical areas and the optimum orientation of test gages may be determined by a brittle coating test.

(b) In tests made for the measurement of collapse load, sufficient measurements must be taken so that all areas which have any reasonable probability of indicating a minimum collapse load are adequately covered. If strain gages are used to determine the collapse load, particular care should be given to assuring that strains (either membrane, bending or a combination) are being measured which are actually indicative of the load carrying capacity of the structure. If distortion measurement devices are used, care should be given to assure that it is the change in cardinal dimensions or deflections which are measured, such as diameter or length extension, or beam or plate deflections that are indicative of the tendency of the structure to actually collapse.

II-1320 REQUIREMENTS FOR PRESSURE GAGES

Pressure gages shall meet the requirements of NB-6400.

II-1330 APPLICATION OF PRESSURE OR LOAD

(a) In tests for determining governing stresses, the internal pressure or mechanical load shall be applied in such increments that the variation of strain with load can be plotted so as to establish the ratio of stress to load in the elastic range. If the first loading results in strains which are not linearly proportional to the load, it is permissible to unload and reload successively until the linear proportionality has been established. When frozen stress photoelastic techniques are used,

Page 29

only one load value can be applied, in which case the load shall not be so high as to result in deformations that invalidate the test results.

(b) In tests made for the measurement of collapse load, the proportional load shall be applied in sufficiently small increments so that an adequate number of data points for each gage are available for statistical analysis in the linear elastic range of behavior. All gages should be evaluated prior to increasing the load beyond this value. A least square fit (regression) analysis shall be used to obtain the best fit straight line, and the confidence interval shall be compared to preset values for acceptance or rejection of the strain gage or other instrumentation. Unacceptable instrumentation will be replaced and the replacement instrumentation tested in the same manner.

(c) After all instrumentation has been deemed acceptable, the test should be continued on a strain or displacement controlled basis with adequate time permitted between load changes for all metal flow to be completed.

II-1400 INTERPRETATION OF RESULTS

II-1410 INTERPRETATION TO BE ON ELASTIC BASIS

The experimental results obtained shall be interpreted on an elastic basis to determine the stresses corresponding to the design loads; that is, in the evaluation of stresses from strain gage data, the calculations shall be performed under the assumption that the material is elastic. The elastic constants used in the evaluation of experimental data shall be those applicable to the test material at the test temperature.

II-1420 REQUIRED EXTENT OF STRESS ANALYSIS

The extent of experimental stress analysis performed shall be sufficient to determine the governing stresses for which design values are unavailable, as described in II-1111. When possible, combined analytical and experimental methods shall be used to distinguish among primary, secondary, and local stresses so that each combination of categories can be controlled by the applicable stress limit.

II-1430 CRITERION OF COLLAPSE LOAD

(a) For distortion measurement tests, the loads are plotted as the ordinate and the measured deflections are plotted as the abscissa. For strain gage tests, the loads are plotted as the ordinate and the maximum principal strains on the surface as the abscissa.

(b) The least square fit (regression) line as determined from the data in the linear elastic range is drawn on each plot considered. The angle that the regression line makes with the ordinate is called θ . A second straight line, hereafter called the collapse limit line, is drawn through the intersection of the regression line with the abscissa so that it makes an angle $\phi = \tan^{-1} (2 \tan \theta)$ with the ordinate. (See Fig. II-1430-1.) The test collapse load is determined from the maximum principal strain or deflection value at the first data point for which there are three successive data points that lie *outside* of the collapse limit line. This first data point is called the *collapse load point*. The test collapse load is taken as the load on the collapse limit line which has the maximum principal strain or deflection of the collapse load point. The collapse load used for design or evaluation purposes shall be the test collapse load multiplied by the ratio of the material yield strength at Design Temperature (Section II, Part D, Subpart 1, Table Y-1) to the test material yield strength at the test temperature. Careful attention shall be given to the actual as-built dimensions of the test model when correlating the collapse load of the test model to that expected for the actual structure being designed.

II-1500 CYCLIC TESTS

II-1510 WHEN CYCLIC TESTS MAY BE USED

1 Throughout the remainder of this Article, wherever the words component or components are used, they shall be understood to include portions thereof, and also appurtenances and portions thereof.

(a) Experimental methods constitute a reliable means of evaluating the capability of components and appurtenances to withstand cyclic loading. In addition, when it is desired to use higher peak stresses than can be justified by the methods of II-1200 to II-1400 and the fatigue curves of Figs. I-9.0, the adequacy of a component, appurtenance, or portion thereof¹ to withstand cyclic loading may be demonstrated by means of a

Page 30

Page 31

fatigue test. The fatigue test shall not be used, however, as justification for exceeding the allowable values of primary or primary plus secondary stresses.

FIG. II-1430-1 CONSTRUCTION FOR II-1430

FIG. II-1430-1 CONSTRUCTION FOR II-1430

(b) When a fatigue test is used to demonstrate the adequacy of a component or a portion thereof to withstand cyclic loading, a description of the test shall be included in the Design Report. This description shall contain sufficient detail to show compliance with the requirements of this Subarticle.

II-1520 REQUIREMENTS FOR CYCLIC TESTING OF COMPONENTS

The requirements of (a) through (g) below shall be met.

(a) The test component or portion being tested shall be constructed of material having the same composition and subjected to mechanical working and heat treating so as to produce mechanical properties equivalent to those of the material in the prototype component. Geometrical similarity must be maintained, at least in those portions whose ability to withstand cyclic loading is being investigated, and in those adjacent areas which affect the stresses in the portion under test.

(b) The test component or portion thereof shall withstand the number of cycles as set forth in (c) below before failure occurs. Failure is herein defined as a propagation of a crack through the entire thickness, such as would produce a measurable leak in a pressure retaining member.

(c) The minimum number of cycles (hereinafter referred to as test cycles), which the component shall withstand and the magnitude of the loading (hereinafter referred to as the test loading) to be applied to the component during test, shall be determined by multiplying the specified service cycles by a specified factor K_{TN} and the specified service loads by K_{TS} . Values of these factors shall be determined by means of the testing parameters ratio diagram, the construction of which is given in (1) through (5) below and is illustrated in Fig. II-1520(c)-1.

(1) Project a vertical line from the specified service cycles N_D on the abscissa of S_a of Figs. I-9.0 to an ordinate value of K_s [II-1520(g)] times S_{aD} . Label this point *A*.

(2) Extend a horizontal line through the point *D* until its length corresponds to an abscissa value of K_n [II-1520(g)] times N_D . Label this point *B*.

(3) Connect the points *A* and *B*. The segments *AB* embrace all the allowable combinations K_{TS} and K_{TN} [see II-1520(d) for accelerated testing]. Any point *C* on this segment may be chosen at the convenience of the tester. Referring to Fig. II-1520(c)-1, the factors K_{TS} and K_{TN} are defined by:

$$K_{TS} = \frac{\text{Value of Ordinate at Point A}}{\text{Value of Ordinate at Point D}}$$

and

$$K_{TN} = \frac{\text{Value of Abscissa at Point } B}{\text{Value of Abscissa at Point } D}$$

thus,

$$P_T (\text{test loading}) = K_{TS} \times \text{specified service loading}$$

$$N_T (\text{test cycles}) = K_{TN} \times \text{specified service cycles}$$

(4) It should be noted that, if the test article is not a full size component but a geometrically similar model, then the value P_T shall be adjusted by the appropriate scale factor to be determined from structural similitude principles if the loading is other than pressure. The number of cycles that the component shall withstand during this test without failure shall not be less than N_T while subjected to a cyclic test loading P_T which shall be adjusted, if required, using model similitude principles if the component is not full size.

(5) In certain instances, it may be desirable (or possible) in performing the test to increase only the loading or number of cycles, but not both, in which event two special cases of interest result from the above general case, as described in (e) and (f) below.

(d) Accelerated fatigue testing (test cycles N_T are less than design cycles N_D) may be conducted if the design cycles N_D are greater than 10^4 and the testing conditions are determined by the procedures of (1) through (3) below which are illustrated in Fig. II-1520(c)-2. In this figure, the points A , B , and D correspond to similar labeled points in Fig. II-1520(c)-1.

(1) The minimum number of test cycles N_{Tmin} shall be

$$N_{Tmin} = 10^2 \sqrt{N_D}$$

Project a vertical line through N_{Tmin} on the abscissa of S_a versus N diagram such that it intersects and extends beyond the fatigue design curve.

(2) Construct a curve through the point A and intersect the vertical projection of N_T [II-1520(d)(1)] by multiplying every point on the fatigue design curve by the factor K_S [II-1520(g)]. Label the intersection of this curve and the vertical projection of N_{Tmin} as A' .

(3) Any point C on the segment A', A, B determines the allowable combinations of K_{TS} and K_{TN} . The factors

Page 32

Page 33

FIG. II-1520(c)-1 CONSTRUCTION OF THE TESTING PARAMETERS RATIO DIAGRAM

FIG. II-1520(c)-1 CONSTRUCTION OF THE TESTING PARAMETERS RATIO DIAGRAM

K_{TS} and K_{TN} are obtained in the same manner as in II-1520(c).

FIG. II-1520(c)-2 CONSTRUCTION OF THE TESTING PARAMETERS RATIO DIAGRAM FOR ACCELERATED TESTS

FIG. II-1520(c)-2 CONSTRUCTION OF THE TESTING PARAMETERS RATIO DIAGRAM FOR ACCELERATED TESTS

(e) Case 1 (Factor Applied to Cycles Only). In this case, $K_{TS} = 1$ and

$$K_{TN} = \frac{\text{Value of Abscissa at Point C}}{\text{Value of Abscissa at Point A}}$$

The number of test cycles that the component shall withstand during this test shall not be less than $N_T = K_{TN} \times$ specified service cycles, while subjected to the cyclic design service loading, adjusted as required, if a model is used.

(f) Case 2 (Factor Applied to Loading Only). In this case, $K_{TN} = 1$ and

$$K_{TS} = \frac{\text{Value of the Ordinate at Point D}}{\text{Value of the Ordinate at Point A}}$$

The component shall withstand a number of cycles at least equal to the number of specified service cycles, while subjected to a cyclic test loading $P_N = K_{TS} \times$ specified service loading, again adjusted as required, if a model is used.

(g) The values of K_s and K_n are the multiples of factors which account for the effects of size, surface finish, cyclic rate, temperature, and the number of replicate tests performed. They shall be determined as follows:

$$K_s = K_{sl} \times K_{sf} \times K_{sc} \times K_{st} \times K_{ss}$$

but shall never be allowed to be less than 1.25 and

$$K_n = K_s^{4.3}$$

but shall never be allowed to be less than 2.6, where

K_{sl}

= factor for the effect of size on fatigue life

= $1.5 - 0.5 (LM/LP)$, where LM/LP is the ratio of linear model size to prototype size

K_{sf}

= factor for the effect of surface finish

= $1.175 - 0.175 (SFM/SFP)$, where SFM/SFP is the ratio of model surface finish to prototype surface finish, in. $\times 10^{-6}$ arithmetic average (AA)

K_{st}

= factor for the effect of test temperature

K_{ss}

= ($S_d N$ at test temperature) / ($S_d N$ at Design Temperature),
where $S_d N$ equals S_a from applicable fatigue curve at N cycles

= factor for the statistical variation in test results

= $1.470 - 0.044 \times \text{number of replicate tests}$

K_{sc}

= factor for differences in design fatigue curves at various temperatures

No value of K_{sp} , K_{sf} , K_{sc} , K_{sp} , or K_{ss} less than 1.0 may be used in calculating K_s .

II-1600 DETERMINATION OF FATIGUE STRENGTH REDUCTION FACTORS

II-1610 PROCEDURES

Experimental determination of fatigue strength reduction factors shall be in accordance with the procedures of (a) through (e) below.

(a) The test part shall be fabricated from a material within the same P-Number grouping of QW-442 of Section IX and shall be subjected to the same heat treatment as the component.

(b) The stress level in the specimen shall be such that the stress intensity does not exceed the limit prescribed by NB-3222.2 and so that failure does not occur in less than 1000 cycles.

(c) The configuration, surface finish, and stress state of the specimen shall closely simulate those expected in the components. In particular, the stress gradient shall not be more abrupt than that expected in the component.

(d) The cyclic rate shall be such that appreciable heating of the specimen does not occur.

(e) The fatigue strength reduction factor shall preferably be determined by performing tests on notched and unnotched specimens and calculated as the ratio of the unnotched stress to the notched stress for failure.

II-1700 EXPERIMENTAL STRESS ANALYSIS OF OPENINGS

II-1710 GENERAL REQUIREMENTS

The stress intensities for opening configurations which do not meet the requirements of NB-3331, NB-3338.2(d), or NB-3339.1 shall be determined in accordance with the methods of this Subarticle.

II-1720 APPLICABILITY OF AVAILABLE EXPERIMENTAL DATA

In accordance with II-1112 reevaluation is not required for configurations for which there are available detailed experimental results that are consistent with the requirements of this Appendix. In order that available

Page 35

experimental data may be interpreted as providing information pertinent to the analysis of slightly different configurations, thereby possibly minimizing the need for additional investigations, the guidelines of II-1730 are presented.

II-1730 GUIDELINES FOR USE OF AVAILABLE EXPERIMENTAL DATA

II-1731 Effect of d/D Ratio

For an unreinforced opening or for an opening where the reinforcement is provided primarily by a uniform increase in component wall thickness, the stresses around the opening will increase with increasing d/D ratio of the opening (diameter of nozzle or opening to diameter of shell). Therefore, experimental data for a small d/D ratio cannot be safely applied to a larger d/D ratio but can be applied to a smaller d/D ratio provided the experiments were made at a d/D ratio < 0.5 .

II-1732 Effect of D/T Ratio

For an unreinforced opening or for an opening where the reinforcement is provided primarily by a uniform increase in component wall thickness, the stresses around the opening will increase with increasing D/T ratio (thinner shell component). Therefore, experimental data for a relatively small D/T ratio cannot be safely applied to a larger D/T ratio but can be applied to a smaller D/T ratio.

II-1733 Proximity to Gross Discontinuities

Generally, the stress data available in the literature are applicable only to single openings. Such data shall be considered valid only for a connection sufficiently removed from another nozzle, opening, flange, or other major discontinuity so that superposition of stresses will not produce an unacceptable value of stress intensity.

II-1734 Requirements for Fillets

Stresses at the outside juncture of a nozzle and shell are greatly influenced by the fillet or transition at the juncture. Generally speaking, stress data available in the literature are for certain specific fillet radii. Other factors being equal, these stress data may be considered valid for fillet radii equal to or greater than those used in the test but shall not be considered valid for smaller fillet radii or undefined fillets and transitions such as for a triangular weld fillet, as commonly used.

II-1800 EXPERIMENTAL DETERMINATION OF STRESS INDICES FOR PIPING

In course of preparation. Pending publication, stress indices for piping shall be determined in accordance with the rules of NB-3680.

II-1900 EXPERIMENTAL DETERMINATION OF FLEXIBILITY FACTORS

In course of preparation. Pending publication, flexibility factors shall be determined in accordance with the rules of NB-3686

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 MA APP III

APPENDIX III BASIS FOR ESTABLISHING DESIGN STRESS INTENSITY VALUES AND ALLOWABLE STRESS VALUES

Page 37

ARTICLE III-1000 INTRODUCTION

III-1100 DERIVATION OF VALUES AND THEIR TABULAR ORGANIZATION

III-1110 RESPONSIBILITY FOR ASSIGNING STRESS INTENSITY AND ALLOWABLE STRESS VALUES

(a) The Boiler and Pressure Vessel Committee evaluates the available data and assigns stress values for materials in accordance with the basis given in this Article.

(b) Where suitable test data on a specification material are not available, the Committee may base design stress values on the available data for similar materials or on an evaluation of known experience with the material.

III-1120 DERIVATION OF STRESS INTENSITY AND ALLOWABLE STRESS VALUES

The values are obtained by applying factors to the mechanical properties of the materials. Consideration is given to the minimum properties specified and the properties at various temperatures as determined by tests on specimens of the material. For all materials, and especially those whose properties are affected by heat treatment, the data for establishing allowable stresses are from test specimens that are representative of the material supplied in accordance with the

specification including the specified heat treatment.

III-1130 LOCATION AND APPLICATION OF STRESS INTENSITY, ALLOWABLE STRESS, AND YIELD STRENGTH VALUES

III-1131 Location

All stress intensity, allowable stress, and yield strength values for use in design under the rules of this Section are given in Section II, Part D. These values are grouped according to temperature. In every application of the values, the temperature is to be understood as being the actual metal temperature.

III-1132 Application

III-1132.1 Design Stress Intensity Values.

Design stress intensity values are given in Section II, Part D, Subpart 1, Tables 2A and 2B for Class 1 components and for Class 1 plate and shell type component supports.

III-1132.2 Allowable Stress Values

(a) Allowable stress values are given in Section II, Part D, Subpart 1, Tables 1A and 1B for Class 2 and 3 components and for Class 2, 3, and MC plate and shell type supports.

(b) Allowable stress values for linear type and component standard supports of all classes of construction except Class 1 plate and shell type component supports (III-1132.1) are derived from the yield strength values given in Section II, Part D, Subpart 1, Table Y-1 by applying the stipulated design factors given in NF-3300.

III-1132.3 Design Stress Intensity and Allowable Stress Values.

The design stress intensity and allowable stress values for Class MC vessels are given in Section II, Part D, Subpart 1, Tables 1A and 1B, except that 90% of the yield strength at temperature shall not be exceeded. Only the material specifications and grades listed in Table NE-2121(a)-1 and bolting material specifications listed in Table NE-2121(a)-2 may be used for Class MC construction.

Page 40

ARTICLE III-2000 DESIGN STRESS INTENSITY VALUES FOR CLASS 1 COMPONENTS

III-2100 MECHANICAL PROPERTY CRITERIA

III-2110 FOR MATERIALS OTHER THAN BOLTING

(a) The mechanical properties considered and factors applied for Section II, Part D, Subpart 1, Tables 2A and 2B are given in that Section.

(b) The upper temperature limit for the tabulated design stress intensity values in Section II, Part D, Subpart 1, Tables 2A and 2B are the temperatures to the next lowest 50°F (28°C) increment at which the creep rate or the stress rupture effects would produce design stresses lower than those from tensile and yield strength data.

III-2120 FOR BOLTING MATERIALS

For bolting materials, the stress values in Section II, Part D, Subpart 1, Table 4 are based on one-third of the minimum specified yield strength at room temperature or one-third of the yield strength at temperature up to a temperature of 800°F (427°C).

III-2200 FATIGUE STRENGTH CRITERIA FOR ALL MATERIALS

The fatigue curves of Figs. I-9.0 are obtained from uniaxial strain cycling data in which the imposed strain amplitude (half range) is multiplied by the elastic modulus to put the values in stress units. A best fit to the experimental data is obtained by

applying the method of least squares to the logarithms of the stress values. The curves are adjusted where necessary to include the maximum effect of mean stress. The design stress intensity values are obtained from the best fit curve by applying a factor of 2 on stress or a factor of 20 on cycles, whichever is the more conservative at each point. Figure I-9.1 is applicable to the carbon and low alloy steels; Figs. I-9.2 and I-9.3 are applicable to the high alloy steels and nonferrous alloys listed in Section II, Part D, Subpart 1, Tables 2A and 2B; and Fig. I-9.4 applies to bolting materials listed in Section II, Part D, Subpart 1, Table 4.

We certify that the statements made in this report are correct and that this installation conforms to the rules for construction of the ASME Code, Section III, Division 1, and was performed in accordance with the documents listed in 8 above.	
N or NA Certificate of Authorization No. _____ Expires _____	
Date _____	Name _____ (N or NA Certificate Holder)
Signed _____ (authorized representative)	
71 CERTIFICATE OF INSTALLATION INSPECTION	
I, the undersigned, holding a valid commission issued by the National Board of Boiler and Pressure Vessel Inspectors and the State or Province of _____ and employed by _____	
of _____ have inspected the installation of the items described in this Data Report on _____ and state that to the best of my knowledge and belief, the Certificate of Authorization Holder has performed this installation in accordance with the ASME Code, Section III, Division 1.	
By signing this certificate, neither the inspector nor his employer makes any warranty, expressed or implied, concerning the installation described in this Data Report. Furthermore, neither the inspector nor his employer shall be liable in any manner for any personal injury or property damage or a loss of any kind arising from or connected with this inspection.	
Date _____	Signed _____ (Authorized Nuclear Inspector)
Commissions 67 _____ (Nat'l. Bd. (incl. endorsements) and state or prov. and no. 1)	
69 CERTIFICATE OF COMPLIANCE FOR OVERALL RESPONSIBILITY	
Following completion of the above, the Certificate of Authorization Holder accepting overall responsibility for the piping system shall complete the following statement:	
We certify that the statements made by this report are correct and that the piping system conforms to the rules for construction of the ASME Code, Section III, Division 1.	
N Certificate of Authorization No. _____ Expires _____	
Date _____	Name _____ (N Certificate Holder)
Signed _____ (authorized representative)	
68 CERTIFICATE OF INSPECTION	
I, the undersigned, holding a valid commission issued by the National Board of Boiler and Pressure Vessel Inspectors and the State or Province of _____ and employed by _____	
of _____ have inspected the piping system described in this Data Report on _____ and state that to the best of my knowledge and belief, the Certificate Holder has constructed this piping system in accordance with the ASME Code, Section III, Division 1.	
By signing this certificate, neither the inspector nor his employer makes any warranty, expressed or implied, concerning the piping system described in this Data Report. Furthermore, neither the inspector nor his employer shall be liable in any manner for any personal injury or property damage or a loss of any kind arising from or connected with this inspection.	
Date _____	Signed _____ (Authorized Nuclear Inspector)
Commissions 67 _____ (Nat'l. Bd. (incl. endorsements) and state or prov. and no. 1)

59

DESIGNER'S REPORT OF CERTIFICATION

I, the undersigned, representing the Designer and employed by have examined and evaluated the Construction Report for the component described in this Data Report. Following evaluation, the Construction Report has been certified and to the best of my knowledge and belief the Constructor has constructed this component in accordance with the rules of the ASME Code, Section III, Division 2, and the construction specifications listed herein, and these construction specifications meet the requirements of the Design Specification.

Date Signed (authorized representative)

P.E. State Reg. no.

70

CERTIFICATE OF CONSTRUCTION COMPLIANCE

We certify that the statements made in this report are correct and that all details of materials, construction, and workmanship of this component conform to the rules for construction of the ASME Code, Section III, Division 2, and the Construction Specifications listed herein.

Certificate of Authorization No. Expires

Date Constructor (In Certificate Holder) Signed (authorized representative)

71

CERTIFICATE OF INSPECTION

I, the undersigned, holding a valid commission issued by the National Board of Boiler and Pressure Vessel Inspectors and the State or Province of and employed by of have inspected the concrete reactor vessel or containment described in this Constructor's Data Report and state that to the best of my knowledge and belief this component has been constructed in accordance with the ASME Code, Section III, Division 2.

By signing this certificate neither the Authorized Inspector nor his employer makes any warranty, expressed or implied, concerning the component described in this report. Furthermore, neither the Authorized Inspector nor his employer shall be liable in any manner for any personal injury or property damage or loss of any kind arising from or connected with this inspection.

Date Signed (Authorized Nuclear Inspector) Commissions 67 (Nat'l. Bd. (incl. endorsements) and state or province and no.)

APPENDIX VI ROUNDED INDICATIONS

Page 81

ARTICLE VI-1000 ROUNDED INDICATIONS

VI-1100 ACCEPTANCE STANDARDS FOR RADIOGRAPHICALLY DETERMINED ROUNDED INDICATIONS IN WELDS

VI-1110 APPLICABILITY OF THESE STANDARDS

These standards are applicable to ferritic, austenitic, and nonferrous material.

VI-1120 TERMINOLOGY

VI-1121 Rounded Indications

Indications with a maximum length of three times the width or less on the radiograph are defined as rounded indications. These indications may be circular, elliptical, conical, or irregular in shape and may have tails. When evaluating the size of an indication, the tail shall be included. The indication may be from any source in the weld, such as porosity, slag, or tungsten.

VI-1122 Aligned Indications

A sequence of four or more rounded indications shall be considered to be aligned when they touch a line parallel to the length of the weld drawn through the center of the two outer rounded indications.

VI-1123 Thickness t

t is the thickness of the weld, of the pressure retaining material, or of the thinner of the sections being joined, whichever is least. If a full penetration weld includes a fillet weld, the thickness of the fillet weld throat shall be included in t .

**TABLE VI-1132-1

> 2	0.156	0.375	0.063

TABLE VI-1132-1 MAXIMUM SIZE OF NONRELEVANT INDICATIONS AND ACCEPTABLE ROUNDED INDICATIONS - EXAMPLES ONLY

VI-1130 ACCEPTANCE CRITERIA

VI-1131 Image Density

Density within the image of the indication may vary and is not a criterion for acceptance or rejection.

VI-1132 Relevant Indications

(See Table VI-1132-1 for Examples)

Only those rounded indications which exceed the following dimensions shall be considered relevant:

$\frac{1}{10}t$ for t less than $\frac{1}{8}$ in. (3.2 mm);

$\frac{1}{64}$ in. (0.4 mm) for t equal to $\frac{1}{8}$ - $\frac{1}{4}$ in. (3.2-6 mm), inclusive;

$\frac{1}{32}$ in. (0.8 mm) for t greater than $\frac{1}{4}$ -2 in. (6-51 mm), inclusive;

$\frac{1}{16}$ in. (1.6 mm) for t greater than 2 in. (51 mm).

Page 84

VI-1133 Maximum Size of Rounded Indication

(See Table VI-1132-1 for Examples)

The maximum permissible size of any indication shall be $\frac{1}{4}t$ or $\frac{5}{32}$ in. (4 mm), whichever is less, except that an isolated indication separated from an adjacent indication by 1 in. (25 mm) or more may be $\frac{1}{3}t$ or $\frac{1}{4}$ in. (6 mm), whichever is less. For t greater than 2 in. (51 mm), the maximum permissible size of an isolated indication shall be increased to $\frac{3}{8}$ in. (10 mm).

VI-1134 Aligned Rounded Indications

Aligned rounded indications are acceptable when the summation of the diameters of the indications is less than t in a length of $12t$ (see Fig. VI-1134-1). The length of groups of aligned rounded indications and the spacing between the groups shall meet the requirements of Fig. VI-1134-2.

VI-1135 Spacing

The distance between adjacent rounded indications is not a factor in determining acceptance or rejection, except as required for isolated indications or groups of aligned indications.

VI-1136 Rounded Indication Charts

(a) The rounded indications as determined from the radiographic film shall not exceed that shown in the charts.

(b) The charts in Figs. VI-1136-1 through VI-1136-6 illustrate various types of assorted, randomly dispersed, and clustered rounded indications for different weld thicknesses greater than $\frac{1}{8}$ in. (3.2 mm). These charts represent the maximum acceptable concentration limits for rounded indications.

(c) The chart for each thickness range represents full-scale 6 in. (152 mm) radiographs and shall not be enlarged or reduced. The distributions shown are not necessarily the patterns that may appear on the radiograph, but are typical of the concentration and size of indications permitted.

VI-1137 Weld Thickness t Less Than $\frac{1}{8}$ in. (3.2 mm)

For t less than $\frac{1}{8}$ in. (3.2 mm) the maximum number of rounded indications shall not exceed 12 in a 6 in. (152 mm) length of weld. A proportionally fewer number of indications shall be permitted in welds less than 6 in. (152 mm) in length.

VI-1138 Clustered Indications

The illustrations for clustered indications show up to four times as many indications in a local area, as that shown in the illustrations for random indications. The length of an acceptable cluster shall not exceed the lesser of 1 in. (25 mm) or $2t$. Where more than one cluster is present, the sum of the lengths of the clusters shall not exceed 1 in. (25 mm) in a 6 in. (152 mm) length of weld.

Page 85

FIG. VI-1134-1 ALIGNED ROUNDED INDICATIONS

The sum of the group lengths shall be less than t in a length of $12 t$.

Maximum Group Length

$L = 1/4$ in. for t less than $3/4$ in.

$L = 1/3 t$ for t equal to $3/4$ in. to $2 1/4$ in.

$L = 3/4$ in. for t greater than $2 1/4$ in.

Minimum Group Spacing

$3L$ where L is the length of the longest adjacent group being evaluated.

FIG. VI-1134-2 GROUPS OF ALIGNED ROUNDED INDICATIONS

APPENDIX XI RULES FOR BOLTED FLANGE CONNECTIONS FOR CLASS 2 AND 3 COMPONENTS AND CLASS MC VESSELS

Page 93

Page 94

ARTICLE XI-1000 INTRODUCTION

XI-1100 GENERAL REQUIREMENTS

[98]

XI-1110 SCOPE

(a) The rules in Appendix XI apply specifically to the design of bolted flange connections for Class 2 and 3 components and Class MC vessels, and are to be used in conjunction with the applicable requirements in Subsections NC, ND, and NE. These rules provide only for hydrostatic end loads and gasket seating loads. For a discussion of design considerations for bolted flange connections, see Appendix XII.

(b) Only circular flanges designated Class RF are covered by the rules of Appendix XI. The design procedures for Class RF flanges, as defined in XI-3211, are given in XI-3200. For Class FF flanges, see Appendix L.

(c) The flange design methods stipulated in this Appendix are primarily applicable to circular flanges under internal pressure. However, Class RF flanges may be used under external pressure when designed in accordance with XI-3260.

[98]

XI-1120 ELEMENTS INVOLVED IN FLANGE DESIGN

XI-1121 General Considerations

This method of designing a flange involves the selection of the gasket material, type and dimensions, flange facing, bolting, hub proportions, flange width, and flange thickness (footnote 1, XI-3221.1). Flange dimensions shall be such that the stresses in the flange, calculated in accordance with XI-3240, do not exceed the allowable flange stresses specified in XI-3250 for Class RF flanges. All calculations shall use dimensions in the corroded condition.

XI-1122 Conditions for Which Design Calculations Shall Be Made

In the design of a bolted flange connection, complete calculations shall be made for two separate and independent sets of conditions which are defined in the following subparagraphs.

[98]

XI-1122.1 Design Conditions.

The Design Conditions are those required to resist the hydrostatic end force of the Design Pressure tending to part the joint and to maintain on the gasket or joint contact surface sufficient compression to assure a tight joint, all at the Design Temperature. The minimum load is a function of the Design Pressure, the gasket material, and the effective gasket or contact area to be kept tight under pressure [as calculated by Eq. (1) in XI-3221.1], and determines one of the two requirements for the amount of bolting A . This load is also used for the design of the flange in Eq. (3) in XI-3223.

[98]

XI-1122.2 Gasket Seating Conditions.

The gasket seating conditions are those existing when the gasket or joint contact surface is seated by applying initial load with the bolts when assembling the joint, at atmospheric temperature and pressure. The minimum initial load considered to be adequate for proper seating is a function of the gasket material and the effective gasket or contact area to be seated [as calculated by Eq. (2) in XI-3221.2], and determines the other of the two requirements for the amount of bolting A_{m2} . For the design of the flange, this load is modified in Eq. (4) in XI-3223 to take account of the Design Conditions when they govern the amount of bolting required A_m , as well as the amount of bolting actually provided A_b .

Page 96

XI-1123 Bolted Flange Connections to External Piping

It is recommended that bolted flange connections conforming to the standards¹ listed in NC-3362, ND-3362, and NE-3362, as applicable, be used for connections to external piping. These standards may be used for other bolted flange connections within the limits of size in the standards and the pressure-temperature ratings permitted in Subsections NC, ND, or NE.

¹ The ratings in these standards are based on the hub dimensions given or on the minimum specified thickness of flanged fittings of integral construction. Flanges fabricated from rings may be used in place of the hub flanges in these standards provided that their strength, calculated by the rules in this Appendix, is not less than that calculated for the corresponding size of hub flange.

Page 97

ARTICLE XI-2000 MATERIALS FOR BOLTED FLANGE CONNECTIONS

XI-2100 MATERIAL REQUIREMENTS

XI-2110 GENERAL REQUIREMENTS

Materials used in the construction of bolted flange connections shall comply with the material requirements given in Subsections NC, ND, or NE, as applicable.

XI-2120 HEAT TREATMENT OF FLANGES

Flanges made from ferritic steel and designed in accordance with this Appendix shall be given a normalizing or full annealing heat treatment when the thickness of the flange section exceeds 3 in. (76 mm).

XI-2130 WELDABILITY OF FLANGES AND POSTWELD HEAT TREATMENT

Material on which welding is to be performed shall be proved of good weldable quality. Satisfactory qualification of the welding procedure under Section IX is considered as proof. Welding shall not be performed on steel that has a carbon content greater than 0.35%. All welding on flange connections shall comply with the requirements for postweld heat treatment given in Subsections NC, ND, or NE, as applicable.

[98]

XI-2140 FABRICATED HUBBED FLANGES

Fabricated hubbed flanges shall be in accordance with (a) through (c) below.

(a) Hubbed flanges may be fabricated from a hot-rolled or -forged billet. The axis of the finished flange shall be parallel to the long axis of the original billet. (This is not intended to imply that the axis of the finished flange and the original billet must be concentric).

(b) Hubbed flanges, except as permitted in (a), shall not be machined from plate or bar stock material unless the material has been formed into a ring and, further, provided that:

(1) in a ring formed from plate, the original plate surfaces are parallel to the axis of the finished flange (this is not

intended to imply that the original plate surface be present in the finished flange);

(2) the joints in the ring are welded butt joints that conform to the requirements of the applicable Subsection. The thickness to be used to determine postweld heat treatment and radiography requirements shall be the lesser of t or $(A - B)/2$, when these symbols are as defined in XI-3130.

(c) The back of the flange and the outer surface of the hub shall be examined by the magnetic particle method (NC-2545) or the liquid penetrant method (NC-2546) to ensure that these surfaces are free from defects.

[98]

XI-2150 BOLTING MATERIALS

Bolts, studs, nuts, and washers shall comply with the requirements of the applicable Subsection. It is recommended that bolts and studs not be smaller than $\frac{1}{2}$ in. (13 mm). If bolts or studs smaller than $\frac{1}{2}$ in. (13 mm) are used, ferrous bolting material shall be of alloy steel. Precautions shall be taken to avoid overstressing small diameter bolts.

Page 98

ARTICLE XI-3000 DESIGN REQUIREMENTS

XI-3100 GENERAL REQUIREMENTS

XI-3110 SCOPE

(a) The rules of XI-3200 apply to Class RF flanges as defined in XI-3212.

(b) The flange design methods given in XI-3210 through XI-3250 apply to Class RF flanges under internal pressure. The flange design methods for Class RF flanges under external pressure or under both internal and external pressure are given in XI-3260.

XI-3120 TYPES OF FLANGES

For purposes of computation, there are three types as described in (a), (b), and (c) below.

(a) *Loose Type Flanges*. This type covers those designs in which the flange has no direct connection to the nozzle neck, vessel, or pipe wall and designs where the method of attachment is not considered to give the mechanical strength equivalent to integral attachment. Figure XI-3120-1 sketches (1), (1a), (2), (3), and (4) show typical loose type flanges and the location of the loads and moments; welds and other details of construction shall satisfy the dimensional requirements given in the referenced sketches.

(b) *Integral Type Flanges*. This type covers designs where the flange is cast or forged integrally with the nozzle neck, vessel, or pipe wall, butt welded thereto, or attached by other forms of arc or gas welding of such a nature that the flange and nozzle neck, vessel, or pipe wall is considered to be the equivalent of an integral structure. In welded construction, the nozzle neck, vessel, or pipe wall is considered to act as a hub. Figure XI-3120-1 sketches (5), (6), (6a), (6b), and (7) show typical integral type flanges and the location of the loads and moments; welds and other details of construction shall satisfy the dimensional requirements given in the referenced sketches.

(c) *Optional Type Flanges*. This type covers designs where the attachment of the flange to the nozzle neck, vessel, or pipe wall is such that the assembly is considered to act as a unit, which shall be calculated as an integral flange, except that for simplicity the designer may calculate the construction as a loose type flange provided none of the following values are exceeded:

$$g_0 = \frac{5}{8} \text{ in. (16 mm)}$$

$$B/g_0 = 300$$

$$P = 300 \text{ psi (2070 kPa)}$$

$$\text{Design Temperature} = 700^\circ\text{F (371}^\circ\text{C)}$$

Figure XI-3120-1 sketches (8), (8a), (8b), and (9) show typical optional type flanges. Welds and other details of construction shall satisfy the dimensional requirements given in those sketches.

[98]

XI-3130 NOMENCLATURE

The nomenclature defined below and shown in Fig. XI-3120-1 is used in the equations for the design of flanges.

A	= outside diameter of flange or, when slotted holes extend to the outside of the flange, the diameter to the bottom of the slots, in.
A_b	= actual total cross-sectional area of bolts at root of thread or section of least diameter under stress, sq in.
A_m	= total required cross-sectional area of bolts taken as the greater of A_{m1} and A_{m2} , sq in.
A_{m1}	= total cross-sectional area of bolts at root of thread or section of least diameter under stress, required for the Design Conditions, sq in. = W_{m1}/S_b

Page 99

Page 101

A_{m2}	= total cross-sectional area of bolts at root of thread or section of least diameter under stress, required for gasket seating, sq in. = W_{m2}/S_a
B	= inside diameter of flange, in. (when B is less than $20g_1$ it will be optional for the designer to substitute B_1 for B in the equation for longitudinal stress S_H)
B_1	= $B + g_1$, in., for loose type hub flanges and also for integral type flanges when f is less than 1 = $B + g_0$, in., for integral type flanges when f is equal to or greater than 1
b	= effective gasket or joint contact surface seating width, in. (footnote ¹ , 3221.1)
b_0	= basic gasket seating width, in. (Table XI-3221.1-2)
C	= bolt circle diameter, in.
c	= basic dimension used for the minimum sizing of welds, in.; equal to t_n or t_D , whichever is less
d	= factor, in. ³ , as follows:

$$= \frac{U}{V} h_0 g_0^2 \text{ for integral type flanges}$$

$$= \frac{U}{V_L} h_0 g_0^2 \text{ for loose type flanges}$$

e	= factor, in.⁻¹, as follows: = F/h_0 for integral type flanges = F_L/h_0 for loose type flanges
F	= factor for integral type flanges (Fig. XI-3240-2)
F_L	= factor for loose type flanges (Fig. XI-3240-4)
f	= hub stress correction factor for integral flanges from Fig. XI-3240-6 (when greater than 1, this is the ratio of the stress in the small end of hub to the stress in the large end; for values below limit of Figure use $f=1$)
G	= diameter at location of gasket load reaction; except as noted in sketch (1) of Fig. XI-3120-1, G is defined as follows for Class RF flanges (see Table XI-3221.1-2): (a) when $b_0 \leq \frac{1}{4}$ in., G is the mean diameter of gasket contact face, in.; (b) when $b_0 > \frac{1}{4}$ in., G is the outside diameter of gasket contact face less $2b$, in.
g_0	= thickness of hub at small end, in.
g_1	= thickness of hub at back of flange, in.
H	= total hydrostatic end force, lb = $0.785G^2P$
H_D	= hydrostatic end force on area inside of flange, lb = $0.785B^2P$
H_G	= gasket load (difference between flange design bolt load and total hydrostatic end force), lb = $W - H$
H_p	= total joint contact surface compression load, lb = $2b \times 3.14GmP$
H_T	= difference between total hydrostatic end force and the hydrostatic end force on area inside of flange, lb

	$= H - H_D$
h	= hub length, in.
h_D	= radial distance, in., from the bolt circle to the circle on which H_D acts, as prescribed in Table XI-3230-1
h_G	= radial distance, in., from gasket load reaction to the bolt circle
	$= (C - G)/2$
h_0	= factor equal to $\sqrt{B g_0}$ in.
h_T	= radial distance, in., from the bolt circle to the circle on which H_T acts, as prescribed in Table XI-3230-1
K	= ratio of outside diameter of flange to inside diameter of flange
	$= A/B$
L	= factor
	=

$$\frac{te + 1}{T} + \frac{t^3}{d}$$

M_D	= component of moment due to H_D in.-lb
	$= H_D h_D$
M_G	= component of moment due to H_G in.-lb
	$= H_G h_G$
M_0	= total moment acting upon the flange, for the Design Conditions or gasket seating, as may apply, in.-lb (XI-3230)
M_T	= component of moment due to H_T in.-lb
	$= H_T h_T$
m	= gasket factor obtained from Table XI-3221.1-1 (footnote ¹ , XI-3221.1)
N	= width, in., used to determine the basic gasket seating width b_0 based upon the possible contact width of the gasket (Table XI-3221.1-2)
P	= Design Pressure, psi (for flanges subject to external pressure see XI-3260 for Class RF flanges)

R	= radial distance from bolt circle to point of intersection of hub and back of flange (integral and hub flanges), in. = $(C - B)/2 - g_1$
S_a	= allowable bolt stress at atmospheric temperature, psi (given in Section II, Part D, Subpart 1, Table 3)

Page 102

S_b	= allowable bolt stress, psi, at Design Temperature (given in Section II, Part D, Subpart 1, Table 3)
S_f	= allowable design stress, psi, for material of flange at Design Temperature (Design Condition) or atmospheric temperature (gasket seating), as applicable (given in Section II, Part D, Subpart 1, Tables 1A and 1B, as applicable)
S_n	= allowable design stress, psi, for material of nozzle neck, vessel, or pipe wall at Design Temperature (Design Condition) or atmospheric temperature (gasket seating) as applicable (given in Section II, Part D, Subpart 1, Tables 1A and 1B, as applicable)
S_H	= calculated longitudinal stress in hub, psi
S_R	= calculated radial stress in flange, psi
S_T	= calculated tangential stress in flange, psi
T	= factor involving K (Fig. XI-3240-1)
t	= flange thickness, in.
t_D	= two times the thickness g_ϕ in., when the design is calculated as an integral flange, or two times the thickness, in., of shell or nozzle wall required for internal pressure when the design is calculated as loose flange, but not less than $1/4$ in.
t_n	= nominal thickness, in., of shell or nozzle wall to which flange or lap is attached, less corrosion allowance
U	= factor involving K (Fig. XI-3240-1)
V	= factor for integral type flanges (Fig. XI-3240-3)
V_L	= factor for loose type flanges (Fig. XI-3240-5)
W	= flange design bolt load, lb, for the Design Conditions or gasket seating as applicable (XI-3223)
W_{m1}	= minimum required bolt load, lb, for the Design Conditions (XI-3220)
W_{m2}	= minimum required bolt load, lb, for gasket seating (XI-3220)
w	= width, in., used to determine the basic gasket seating width b_ϕ based upon the contact width between the flange facing and the gasket (Table XI-3221.1-2)
Y	= factor involving K (Fig. XI-3240-1)

y

= gasket or joint contact surface unit seating load, psi
(footnote ¹, XI-3221.1)

Z

= factor involving K (Fig. XI-3240-1)

FIG. XI-3120-1 TYPES OF FLANGES (CONT'D)

FIG. XI-3120-1 TYPES OF FLANGES (CONT'D)

XI-3200 CLASS RF FLANGE DESIGN

XI-3210 GENERAL REQUIREMENTS

[98]

XI-3211 Definition of Class RF Flanges

Class RF flanges are circular flanges having gaskets which are entirely within the circle enclosed by the bolt holes and which have no contact outside this circle.

[98]

[98]

XI-3212 Acceptability

The requirements for acceptability of Class RF flange design are given in (a) and (b) below.

(a) The design shall be such that the general design requirements of NC-3100, ND-3100, or NE-3100, as appropriate, and the specific design requirements of this Subarticle are met.

(b) The designs shall be limited to the types of flanges defined in XI-3120.

[98]

XI-3220 BOLT LOADS AND BOLT AREAS

[98]

XI-3221 Determination of Bolt Loads

In the design of a bolted flange connection, calculations shall be made for each of the two conditions, namely, Design Loadings and gasket seating loads, and the more severe condition shall control. In the design of flange pairs used to contain a tubesheet of a heat exchanger, or any similar design where the flanges and/or gaskets may not be the same, loads shall be determined for the most severe condition of Design Loadings and/or gasket seating loads applied to each side at the same time. This most severe condition may be gasket seating on one flange with Design Loadings on the other, gasket seating on each flange at the same time, or Design Loadings on each flange at the same time.

[98]

XI-3221.1 Bolt Load for Design Conditions.

The required bolt load for the Design Conditions W_{m1} shall be sufficient to resist the hydrostatic end force H exerted by the Design Pressure on the area bounded by the diameter of gasket reaction and, in addition, to maintain on the gasket or joint contact surface a compression load H_p which experience has shown to be sufficient to ensure a tight joint. This compression load is expressed as a multiple m of the internal pressure. Its value is a function of the gasket material and construction.² The required bolt load for the Design Conditions W_{m1} is determined in accordance with Eq. (1):

$$(1) W_{m1} = H + H_p = 0.785G^2P + (2b \times 3.14GmP)$$

² Tables XI-3221.1-1 and XI-3221.1-2 give a list of many commonly used gasket materials and contact facings, with suggested values of m , b , and y that have proved satisfactory in actual service.

These values are suggested only and are not mandatory. Values that are too low may result in leakage at the joint, without affecting the safety of the design. The primary proof that the values are adequate is the hydrostatic test.

XI-3221.2 Bolt Load for Gasket Seating Condition.

Before a tight joint can be obtained, it is necessary to

Location of Gasket Load Reaction

NOTES:

- (1) Where serrations do not exceed $\frac{1}{64}$ in. depth and $\frac{1}{32}$ in. width spacing, sketches (1b) and (1d) shall be used.
- (2) The gasket factors listed only apply to flanged joints in which the gasket is contained entirely within the inner edges of the bolt holes.

TABLE XI-3221.1-2 EFFECTIVE GASKET WIDTH²

seat the gasket or joint contact surface properly by applying a minimum initial load under atmospheric temperature conditions without the presence of internal pressure, which is a function of the gasket material and the effective gasket

area to be seated. The minimum initial bolt load W_{m2} required for this purpose shall be determined in accordance with Eq. (2):

$$(2) W_{m2} = 3.14bGy$$

	$\frac{C - B}{2}$	$\frac{C - G}{2}$	$\frac{C - G}{2}$

[98]

TABLE XI-3230-1 MOMENT ARMS FOR FLANGE LOADS

The need for providing sufficient bolt load to seat the gasket or joint contact surfaces in accordance with Eq. (2) will prevail on many low pressure designs and with facings and materials that require a high seating load and where the bolt load computed by Eq. (1) for the Design Conditions is insufficient to seat the joint. Accordingly, it is necessary to furnish bolting and to pretighten the bolts to provide a bolt load sufficient to satisfy both of these requirements, each one

being individually investigated. When Eq. (2) governs, flange proportions will be a function of the bolting instead of internal pressure.

XI-3221.3 Bolt Load When Self-Energizing Gaskets Are Used.

Bolt loads for flanges using gaskets of the self-energizing type differ from those shown above as stipulated in (a) and (b) below.

(a) The required bolt load for the Design Conditions W_{m1} shall be sufficient to resist the hydrostatic end force H exerted by the Design Pressure on the area bounded by the outside diameter of the gasket. H_p is to be considered as zero for all self-energizing gaskets except certain seal configurations which generate axial loads which shall be considered.

(b) $W_{m2} = 0$. Self-energizing gaskets may be considered to require an inconsequential amount of bolting force to produce a seal. Bolting, however, shall be pretightened to provide a bolt load sufficient to withstand the hydrostatic end force H .

XI-3222 Total Required and Actual Bolt Areas A_m and A_b

The total cross-sectional area of bolts A_m required for both the Design Conditions and gasket seating is the greater of the values for A_{m1} and A_{m2} , where $A_{m1} = W_{m1}/S_b$ and $A_{m2} = W_{m2}/S_a$. A selection of bolts to be used shall be made such that the actual total cross-sectional areas of bolts A_b will not be less than A_m .

XI-3223 Flange Design Bolt Load W

The bolt loads used in the design of the flange shall be the values obtained from Eqs. (3) and (4). For Design Conditions,

$$(3) W = W_{m1}$$

For gasket seating,

$$W = \frac{(A_m + A_b) S_a}{2} \quad (4)$$

(4)

In addition to the minimum requirements for safety, Eq. (4) provides a margin against abuse of the flange from overbolting. Since margin against such abuse is needed primarily for the initial bolting up operation, which is done at atmospheric temperature and before application of internal pressure, the flange design is required to satisfy this loading only under such conditions.³

³ Where additional safety against abuse is desired, or where it is necessary that the flange be suitable to withstand the full available bolt load $A_b \times S_b$, the flange may be designed on the basis of this latter quantity.

XI-3230 FLANGE MOMENTS

(a) In the calculation of flange stresses, the moment of a loading acting on the flange is the product of the

Page 107

load and its moment arm. The moment arm is determined by the relative position of the bolt circle with respect to that of

the load producing the moment (Fig. XI-3120-1). No consideration shall be given to any possible reduction in moment arm due to cupping of the flanges or due to inward shifting of the line of action of the bolts as a result thereof.

(b) For the Design Conditions, the total flange moment M_0 is the sum of the three individual moments M_D , M_T , and M_G as defined in XI-3130, and based on the flange design bolt load of Eq. (3) with moment arms as given in Table XI-3230-1.

(c) For gasket seating, the total flange moment M_0 is based on the flange design bolt load of Eq. (4), which is opposed only by the gasket load, in which case:

$$M_0 = W \frac{(C - G)}{2} \quad (5)$$

(5)

XI-3240 CALCULATION OF FLANGE STRESSES

The stresses in the flange shall be determined for both the Design Conditions and gasket seating, whichever controls, in accordance with the equations in (a) or (b) below.

(a) For integral type flanges and all hub type flanges:

Longitudinal hub stress

$$(6) S_H = fM_0/Lg_1^2B$$

Radial flange stress

$$(7) S_R = [(1.33te + 1)M_0]/Lr^2B$$

Tangential flange stress

$$(8) S_T = (YM_0/r^2B) - ZS_R$$

(b) For loose type ring flanges including optional type calculated as loose type having a rectangular cross section:

$$(9) S_T = YM_0/r^2B$$

$$S_R = 0$$

$$S_H = 0$$

[98]

XI-3250 ALLOWABLE FLANGE DESIGN STRESSES

The flange stresses calculated by the equations in XI-3240 shall not exceed the values given in (a) through (f) below.

(a) The longitudinal hub stress S_H shall not be greater than the smaller of $1.5S_f$ or $1.5S_n$ for optional type flanges designed as integral [Fig. XI-3120-1 sketches (8), (8a), (8b), and (9)], and also for integral type flanges [Fig. XI-3120-1 sketch (7)] where the neck material constitutes the hub of the flange.

(b) The longitudinal hub stress S_H shall not be greater than the smaller of $1.5S_f$ or $1.5S_n$ for integral type flanges with hub welded to the neck, pipe, or vessel wall [Fig. XI-3120-1 sketches (6), (6a), and (6b)].

(c) The radial flange stress S_R shall not be greater than S_f .

(d) The tangential flange stress S_T shall not be greater than S_f .

(e) Also $(S_H + S_R)/2$ shall not be greater than S_f and $(S_H + S_P)/2$ shall not be greater than S_f .

(f) In the case of loose type flanges with laps, as shown in Fig. XI-3120-1 sketches (1) and (1a), where the gasket is so located that the lap is subjected to shear, the shearing stress shall not exceed $0.8S_n$ for the material of the lap, as defined in XI-3130. In the case of welded flanges, shown in Fig. XI-3120-1 sketches (3), (4), (7), (8), (8a), and (8b), where the nozzle neck, vessel, or pipe wall extends near to the flange face and may form the gasket contact face, the shearing stress carried by the welds shall not exceed $0.8S_n$. The shearing stress shall be calculated on the basis of W_{m1} or W_{m2} (as defined in XI-3130), whichever is greater. Similar cases where flange parts are subjected to shearing stress shall be governed by the same requirements.

[98]

XI-3260 FLANGES SUBJECT TO EXTERNAL PRESSURE

⁴ When internal pressure occurs only during the required pressure test, the design may be based on external pressure and auxiliary devices such as clamps may be used during the application of the required test pressure.

XI-3261 Flanges for External Pressure Only

The design of flanges for external pressure⁴ only shall be based on the equations given in XI-3240 for internal pressure except that for Design Conditions,

for gasket seating,

$$(11) M_0 = W h_G$$

In Eqs. (10) and (11):

$$W = \frac{A_{m2} + A_b}{2} S_a$$

$$H_D = 0.785 B^2 P_e$$

$$H_T = H - H_D$$

$$H = 0.785 G^2 P_e$$

P_e = external Design Pressure, psi

See XI-3130 for definitions of other symbols.

XI-3262 Flanges for Both External and Internal Pressure

When flanges are subject at different times during service to external or internal pressure, the design shall satisfy the external pressure design requirements⁵ given in XI-3261 and the internal pressure design requirements given elsewhere in this Appendix.

⁵ The combined force of external pressure and bolt loading may plastically deform certain gaskets to result in loss of gasket contact pressure when the connection is depressurized. To maintain a tight joint when the unit is repressurized, consideration should be given to gasket and facing details, so that excessive deformation of the gasket will not occur. Joints subject to pressure reversals, such as in heat exchanger floating heads, are in this type of service.

APPENDIX XII DESIGN CONSIDERATIONS FOR BOLTED
FLANGE CONNECTIONS

Page 117

ARTICLE XII-1000 DESIGN CONSIDERATIONS FOR BOLTED FLANGE CONNECTIONS

XII-1100 CONSIDERATIONS

(a) The primary purpose of the rules for bolted flange connections in Appendix XI is to ensure safety, but there are certain other practical matters to be taken into consideration in order to obtain a serviceable design. One of the most important of these is the proportioning of the bolting, i.e., determining the number and size of the bolts.

(b) In the great majority of designs the practice that has been used in the past should be adequate: to follow the design rules in Appendix XI and tighten the bolts sufficiently to withstand the test pressure without leakage. The considerations presented in the discussion in (c) through (m) below will be important only when some unusual feature exists, such as a very large diameter, a high Design Pressure, a high temperature, severe temperature gradients, an unusual gasket arrangement, and so on.

(c) The maximum allowable stress values for bolting given in Section II, Part D, Subpart 1, Table 3 are design values to be used in determining the minimum amount of bolting required under the rules. However, a distinction must be kept carefully in mind between the design value and the bolt stress that might actually exist or that might be needed for conditions other than the Design Pressure. The initial tightening of the bolts is a prestressing operation, and the amount of bolt stress developed must be within proper limits to ensure, on the one hand, that it is adequate to provide against all conditions that tend to produce a leaking joint and, on the other hand, that it is not so excessive that yielding of the bolts or flanges can produce relaxation that also can result in leakage.

(d) The first important consideration is the need for the joint to be tight in the hydrostatic test. An initial bolt stress of some magnitude greater than the design value therefore must be provided. If it is not, further bolt strain develops during the test, which tends to part the joint and thereby to decompress the gasket enough to allow leakage. The test pressure is usually $1\frac{1}{2}$ times the Design Pressure, and on this basis it may be thought that 50% extra bolt stress above the design value will be sufficient. However, this is an oversimplification because, on the one hand, the safety factor against leakage under test conditions in general need not be as great as under Design Conditions. On the other hand, if a stress-strain analysis of the joint is made, it may indicate that an initial bolt stress still higher than $1\frac{1}{2}$ times the design value is needed. Such an analysis is one that considers the changes in bolt elongation, flange deflection, and gasket load that take place with the application of internal pressure, starting from the prestressed condition. In any event, it is evident that an initial bolt stress higher than the design value may and, in some cases, must be developed in the tightening operation, and it is the intent of Subsections NC, ND, and NE that such a practice is permissible, provided it includes necessary and appropriate provision to ensure against excessive flange distortion and gross crushing of the gasket.

(e) It is possible for the bolt stress to decrease after initial tightening, because of slow creep or relaxation of the gasket, particularly in the case of the softer gasket materials. This may be the cause of leakage in the hydrostatic test, in which case it may suffice merely to retighten the bolts. A decrease in bolt stress can also occur in service at elevated temperatures, as a result of creep in the bolt or flange or gasket material, with consequent relaxation. When this results in leakage under service conditions, it is common practice to retighten the bolts, and sometimes a single such operation or perhaps several repeated at long intervals is sufficient to correct the condition. To avoid chronic difficulties of this nature, however, it is advisable when designing a joint for high temperature service to give attention to the relaxation properties of the materials

Page 120

involved, especially for temperatures where creep is the controlling factor in design.

(f) In the other direction, excessive initial bolt stress can present a problem in the form of yielding in the bolting itself and may occur in the tightening operation to the extent of damage or even breakage. This is especially likely with bolts of small diameter and with bolt materials having a relatively low yield strength. The yield strength of mild carbon steel, annealed austenitic stainless steel, and certain of the nonferrous bolting materials can easily be exceeded with ordinary wrench effort in

the smaller bolt sizes. Even if no damage is evident, any additional load generated when internal pressure is applied can produce further yielding with possible leakage. Such yielding can also occur when there is very little margin between initial bolt stress and yield strength.

(g) An increase in bolt stress, above any that may be due to internal pressure, might occur in service during startup or other transient conditions, or perhaps even under normal service. This can happen when there is an appreciable differential in temperature between the flanges and the bolts or when the bolt material has a different coefficient of thermal expansion than the flange material. Any increase in bolt load due to this thermal effect, superposed on the load already existing, can cause yielding of the bolt material, whereas any pronounced decrease due to such effects can result in such a loss of bolt load as to be a direct cause of leakage. In either case, retightening of the bolts may be necessary, but it must not be forgotten that the effects of repeated retightening can be cumulative and may ultimately make the joint unserviceable.

(h) In addition to the difficulties created by yielding of the bolts as described above, the possibility of similar difficulties arising from yielding of the flange or gasket material, under like circumstances or from other causes, should also be considered.

(i) Excessive bolt stress, whatever the reason, may cause the flange to yield even though the bolts may not yield. Any resulting excessive deflection of the flange, accompanied by permanent set, can produce a leaking joint when other effects are superposed. It can also damage the flange by making it more difficult to effect a tight joint thereafter. For example, irregular permanent distortion of the flange due to uneven bolt load around the circumference of the joint can warp the flange face and its gasket contact surface out of a true plane.

(j) The gasket, too, can be overloaded, even without excessive bolt stress. The full initial bolt load is imposed entirely on the gasket, unless the gasket has a stop ring or the flange face detail is arranged to provide the equivalent. Without such means of controlling the compression of the gasket, consideration must be given to the selection of gasket type, size, and material that will prevent gross crushing of the gasket.

(k) From the foregoing, it is apparent that the bolt stress can vary over a considerable range above the design stress value. The design stress values for bolting have been set at a conservative value to provide a factor against yielding. At elevated temperatures, the design stress values are governed by the creep rate and stress rupture strength. Any higher bolt stress existing before creep occurs in operation will have already served its purpose of seating the gasket and holding the hydrostatic test pressure, all at atmospheric temperature, and is not needed at the Design Pressure and Temperature.

(l) Theoretically, the margin against flange yielding is not as great. The design values for flange materials may be as high as five-eighths or two-thirds of the yield strength. However, the highest stress in a flange is usually the bending stress in the hub or shell and is more or less localized. It is too conservative to assume that local yielding is followed immediately by overall yielding of the entire flange. Even if a plastic hinge should develop, the ring portion of the flange takes up the portion of the load that the hub and shell refuse to carry. Yielding is far more significant if it occurs first in the ring but the limitation in the rules on the combined hub and ring stresses provides a safeguard. In this connection, reference should be made to Note (2) of Section II, Part D, Subpart 1, Tables 1A and 1B which provides guidance in the case of high alloy materials to which a strain limiting factor may have to be applied.

(m) Another very important item in bolting design is the question of whether the necessary bolt stress is actually realized and what special means of tightening, if any, must be employed. Most joints are tightened manually by ordinary wrenching and it is advantageous to have designs that require no more than this. Some pitfalls must be avoided, however. The probable bolt stress developed manually, when using standard wrenches, is:

$$S = 45,000/\sqrt{d}$$

where S is the bolt stress and d is the nominal diameter of the bolt. It can be seen that smaller bolts will have excessive stress unless judgment is exercised in pulling up on them. On the other hand, it will be impossible to develop the desired stress in very large bolts by ordinary hand wrenching. Impact wrenches may prove

serviceable, but, if not, resort may be had to such methods as preheating the bolt or using hydraulically powered bolt tensioners. With some of these methods, control of the bolt stress is possible by means inherent in the procedure, especially if effective thread lubricants are employed, but in all cases the bolt stress can be regulated within reasonable tolerances by measuring the bolt elongation with suitable extensometer equipment. Ordinarily, simple wrenching without verification of the actual bolt stress meets all practical needs, and measured control of the stress is employed only when there is some special or important reason for doing so.

APPENDIX XIII DESIGN BASED ON STRESS ANALYSIS FOR VESSELS DESIGNED IN ACCORDANCE WITH NC-3200

Page 123

ARTICLE XIII-1000 DESIGN BASED ON STRESS ANALYSIS

XIII-1100 GENERAL REQUIREMENTS

XIII-1110 SCOPE

This Appendix is applicable only to the design of Class 2 vessels meeting the requirements of NC-3200.

(a) When a fatigue evaluation is not required (NC-3217), a vessel or a vessel part may be designed using the stress analysis methods given in this Appendix. When a fatigue evaluation is required, this Appendix shall be used together with Appendix XIV, Design Based on Fatigue Analysis for Vessels Designed in Accordance With NC-3200.

(b) Use of the analytical methods contained in the Articles of this Appendix which follow this Article is an acceptable way of obtaining solutions to problems for which these procedures are applicable. Other techniques, analytical or experimental (Appendix II), may be used provided they are either more accurate or more conservative than those contained herein.

XIII-1120 DESIGN ACCEPTABILITY

XIII-1121 Requirements for Design Acceptability

The requirements for the acceptability of a design are given in (a) and (b) below.

(a) The design shall be such that the stresses shall not exceed the limits described in XIII-1140.

(b) For configurations where compressive stresses occur, in addition to the requirement in (a) above, the critical buckling stress shall be taken into account. For the case of external pressure, see NC-3245.

XIII-1122 Basis for Determining Stresses

The equivalent stress at any point in a vessel is the value of stress deduced from the stress condition at the point by means of a theory of failure for comparison with the mechanical properties of the material obtained in tests under uniaxial load. The theory of failure, used in the rules of this Appendix for combining stresses, is the maximum shear stress theory. The maximum shear stress at a point is equal to one-half the difference between the algebraically largest and the algebraically smallest of the three principal stresses at the point.

XIII-1123 Terms Relating to Stress Analysis

Terms used in this Appendix relating to stress analysis are defined in (a) through (r) below.

(a) *Stress Intensity*.¹ Stress intensity is the equivalent intensity of combined stress, or in short, the stress intensity is defined as twice the maximum shear stress. In other words, the stress intensity is the difference between the algebraically largest principal stress and the algebraically smallest principal stress at a given point. Tension stresses are considered positive and compression stresses are considered negative.

(b) *Gross Structural Discontinuity*. Gross structural discontinuity is a source of stress or strain intensification which affects a relatively large portion of a structure and has a significant effect on the overall stress or strain pattern or on the structure as a whole. Examples of gross structural discontinuities are: head-to-shell and flange-to-shell junctions, nozzles

and junctions between shells of different diameters or thicknesses.

(c) *Local Structural Discontinuity*. Local structural discontinuity is a source of stress or strain intensification which affects a relatively small volume of material and does not have a significant effect on the overall stress or strain pattern or on the structure as a whole. Examples are: small fillet radii, small attachments, and partial penetration welds.

1 This definition of stress intensity is not related to the definition of stress intensity applied in the field of Fracture Mechanics.

(d) *Normal Stress*. Normal stress is the component of stress normal to the plane of reference. This is also referred to as direct stress. Usually the distribution of normal stress is not uniform through the thickness of a part, so this stress is considered to be made up in

Page 126

turn of two components, one of which is uniformly distributed and equal to the average value of stress across the thickness of the section under consideration and the other of which varies with the location across the thickness.

(e) *Shear Stress*. Shear stress is the component of stress tangent to the plane of reference.

(f) *Membrane Stress*. Membrane stress is the component of normal stress which is uniformly distributed and equal to the average value of stress across the thickness of the section under consideration.

(g) *Bending Stress*. Bending stress is the variable component of normal stress described in (d) above. The variation may or may not be linear across the thickness.

(h) *Primary Stress*. Primary stress is a normal stress developed by the imposed loading which is necessary to satisfy the laws of equilibrium of external and internal forces and moments. The basic characteristic of a primary stress is that it is not self-limiting. Primary stresses which considerably exceed the yield strength will result in failure or, at least, in gross distortion. A thermal stress is not classified as a primary stress. Primary membrane stress is divided into general and local categories. A general primary membrane stress is one which is so distributed in the structure that no redistribution of load occurs as a result of yielding. Examples of primary stress are as follows:

(1) general membrane stress in a circular cylindrical or a spherical shell due to internal pressure or to distributed live loads;

(2) bending stress in the central portion of a flat head due to pressure.

(i) *Secondary Stress*. Secondary stress is a normal stress or a shear stress developed by the constraint of adjacent parts or by self-constraint of a structure. The basic characteristic of a secondary stress is that it is self-limiting. Local yielding and minor distortions can satisfy the conditions which cause the stress to occur and failure from one application of the stress is not to be expected. Examples of secondary stress are as follows:

(1) general thermal stress [see (m) below];

(2) bending stress at a gross structural discontinuity.

(j) *Local Primary Membrane Stress*. Cases arise in which a membrane stress produced by pressure or other mechanical loading and associated with a discontinuity would, if not limited, produce excessive distortion in the transfer of load to other portions of the structure. Conservatism requires that such a stress be classified as a local primary-membrane stress even though it has some characteristics of a secondary stress. A stressed region may be considered local if the distance over which the membrane stress intensity exceeds $1.1S_m$ does not extend in the meridional direction more than $1.0\sqrt{Rt}$, where R is the minimum midsurface radius of curvature and t is the minimum thickness in the region considered. Regions of local primary stress intensity involving axisymmetric membrane stress distributions which exceed $1.1S_m$ shall not be closer in the meridional direction than $2.5\sqrt{Rt}$, where R is defined as $(R_1 + R_2)/2$ and t is defined as $(t_1 + t_2)/2$, where t_1 and t_2 are the minimum thicknesses at each of the regions considered, and R_1 and R_2 are the minimum midsurface radii of curvature at these regions where the membrane stress intensity exceeds $1.1S_m$. Discrete regions of local primary membrane stress intensity, such as those resulting from concentrated loads acting on brackets, where the membrane stress intensity exceeds $1.1S_m$ shall be spaced so that there is no overlapping of the areas in which the membrane stress intensity exceeds $1.1S_m$.

(k) *Peak Stress*. The basic characteristic of a peak stress is that it does not cause any noticeable distortion and is objectionable only as a possible source of a fatigue crack or a brittle fracture. A stress which is not highly localized falls

into this category if it is of a type which cannot cause noticeable distortion. Examples of peak stress are as follows:

- (1) the thermal stress in the austenitic steel cladding of a carbon steel vessel;
- (2) the thermal stress in the wall of a vessel or pipe caused by a rapid change in temperature of the contained fluid;
- (3) the stress at a local structural discontinuity.

(l) *Load Stress*. Load stress is the stress resulting from the application of a load, such as internal pressure or the effects of gravity, as distinguished from thermal stress.

(m) *Thermal Stress*. Thermal stress is a self-balancing stress produced by a nonuniform distribution of temperature or by differing thermal coefficients of expansion. Thermal stress is developed in a solid body whenever a volume of material is prevented from assuming the size and shape that it normally should under a change in temperature. For the purpose of establishing allowable stresses, two types of thermal stress are recognized, depending on the volume or area in which distortion takes place, as described in (1) and (2) below.

(1) One type of thermal stress is general thermal stress which is associated with distortion of the structure in which it occurs. If a stress of this type, neglecting stress concentrations, exceeds twice the yield strength of the material, the elastic analysis may be invalid and

Page 127

successive thermal cycles may produce incremental distortion. Therefore, this type is classified as secondary stress in Table XIII-1130-1 and Fig. XIII-1141-1. Examples of general thermal stress are as follows:

- (a) stress produced by an axial temperature distribution in a cylindrical shell;
- (b) stress produced by the temperature difference between a nozzle and the shell to which it is attached;
- (c) the equivalent linear stress² produced by the radial temperature distribution in a cylindrical shell.

(2) The other type of thermal stress is local thermal stress which is associated with almost complete suppression of the differential expansion and thus produces no significant distortion. Such stresses shall be considered only from the fatigue standpoint and are therefore classified as local stresses in Table XIII-1130-1 and Fig. XIII-1141-1. In evaluating local thermal stresses the procedures of XIII-1151.1(b) shall be used. Examples of local thermal stresses are as follows:

- (a) the stress in a small hot spot in a vessel wall;
- (b) the difference between the actual stress and the equivalent linear stress resulting from a radial temperature distribution in a cylindrical shell;
- (c) the thermal stress in a cladding material which has a coefficient of expansion different from that of the base metal.

(n) *Total Stress*. Total stress is the sum of the primary, secondary, and peak stress contributions. Recognition of each of the individual contributions is essential to establishment of appropriate limitations.

(o) *Operational Cycle*. An operational cycle is defined as the initiation and establishment of new conditions followed by a return to the conditions that prevailed at the beginning of the cycle. Three types are considered:

- (1) startup-shutdown cycle, defined as any cycle which has atmospheric temperature or pressure as one of its extremes and normal operating conditions as its other extreme;
- (2) the initiation of and recovery from any loadings for which Level A or Level B Service Limits are designated and which are required to be considered in the design;
- (3) normal service cycle, defined as any cycle between startup and shutdown which is required for the vessel to perform its intended purpose.

² Equivalent linear stress is defined as the linear stress distribution which has the same net bending moment as the actual stress distribution.

(p) *Stress Cycle*. Stress cycle is a condition in which the alternating stress difference (XIV-1212) goes from an initial value through an algebraic maximum value and an algebraic minimum value and then returns to the initial value. A single service cycle may result in one or more stress cycles.

(q) *Fatigue Strength Reduction Factor*. Fatigue strength reduction factor is a stress intensification factor which accounts for the effect of a local structural discontinuity (stress concentration) on the fatigue strength. Values for some specific cases, based on experiment, are given elsewhere and in Subsection NC. In the absence of experimental data, the theoretical stress concentration factor may be used.

(r) *Shakedown*. Shakedown of a structure occurs if, after a few cycles of load application, ratcheting ceases. The subsequent structural response is elastic, or elastic-plastic, and progressive incremental inelastic deformation is absent. Elastic shakedown is the case in which the subsequent response is elastic.

(s) *Deformation*. Deformation of a component part is an alteration of its shape or size.

(t) *Inelasticity*. Inelasticity is a general characteristic of material behavior in which the material does not return to its original shape and size after removal of all applied loads. Plasticity and creep are special cases of inelasticity.

(u) *Creep*. Creep is the special case of inelasticity that relates to the stress induced time-dependent deformation under load. Small time-dependent deformations may occur after the removal of all applied loads.

(v) *Plasticity*. Plasticity is the special case of inelasticity in which the material undergoes time-independent nonrecoverable deformation.

(w) *Plastic Analysis*. Plastic analysis is that method which computes the structural behavior under given loads considering the plasticity characteristics of the materials including strain hardening and the stress redistribution occurring in the structure.

(x) *Plastic Analysis - Collapse Load*. A plastic analysis may be used to determine the collapse load for a given combination of loads on a given structure. The following criterion for determination of the collapse load shall be used. A load-deflection or load-strain curve is plotted with load as the ordinate and deflection or strain as the abscissa. The angle that the linear part of the load-deflection or load-strain curve makes with the ordinate is called θ . A second straight line, hereafter called the collapse limit line, is drawn through the origin so that it makes an angle $\phi = \tan^{-1} (2 \tan \theta)$ with the ordinate. The collapse load is the load at the intersection of the load-deflection or load-strain curve and the collapse limit line. If this method is used, particular care should be given to ensure that the strains or deflections that are used are indicative of the load carrying capacity of the structure.

Page 128

(y) *Plastic Instability Load*. The plastic instability load for members under predominantly tensile or compressive loading is defined as that load at which unbounded plastic deformation can occur without an increase in load. At the plastic tensile instability load the true stress in the material increases faster than strain hardening can accommodate.

(z) *Limit Analysis*. Limit analysis is a special case of plastic analysis in which the material is assumed to be ideally plastic (nonstrain-hardening). In limit analysis the equilibrium and flow characteristics at the limit state are used to calculate the collapse load. The two bounding methods which are used in limit analysis are the lower bound approach, which is associated with a statically admissible stress field, and the upper bound approach, which is associated with a kinematically admissible velocity field. For beams and frames the term *mechanism* is commonly used in lieu of *kinematically admissible velocity field*.

(aa) *Collapse Load - Lower Bound*. If, for a given load, any system of stresses can be found which everywhere satisfies equilibrium, and nowhere exceeds the material yield strength, the load is at or below the collapse load. This is the lower bound theorem of limit analysis which permits calculations of a lower bound to the collapse load.

(bb) *Limit Analysis - Collapse Load*. The methods of limit analysis are used to compute the maximum load that a structure assumed to be made of ideally plastic material can carry. At this load, which is termed the collapse load, the deformations of the structure increase without bound.

(cc) *Plastic Hinge*. A plastic hinge is an idealized concept used in Limit Analysis. In a beam or a frame, a plastic hinge is formed at the point where the moment, shear, and axial force lie on the yield interaction surface. In plates and shells a plastic hinge is formed where the generalized stresses lie on the yield surface.

(dd) *Strain Limiting Load*. When a limit is placed upon a strain, the load associated with the strain limit is called the

strain limiting load.

(ee) *Test Collapse Load*. Test collapse load is the collapse load determined by tests according to the criteria given in II-1430 of Section III.

(ff) *Ratcheting*. Ratcheting is a progressive incremental inelastic deformation or strain which can occur in a component that is subjected to variations of mechanical stress, thermal stress, or both.

XIII-1130 DERIVATION OF STRESS INTENSITIES

One requirement for the acceptability of a design [XIII-1121(a)] is that the calculated stress intensities shall not exceed specified allowable limits. These limits differ depending on the stress category (primary, secondary, etc.) from which the stress intensity is derived. This paragraph describes the procedure for the calculation of the stress intensities which are subject to specified limits. The steps in the procedure are given in (a) through (f) below.

(a) At the point on the vessel which is being investigated, choose an orthogonal set of coordinates, such as tangential, longitudinal, and radial, and designate them by the subscripts t , l , and r . The stress components in these directions are then designated σ_t , σ_r , and σ_l for direct stresses and τ_{tl} , τ_{lr} , and τ_{rl} for shear stresses.

(b) Calculate the stress components for each type of loading to which the part will be subjected and assign each set of stress values to one or a group of the following categories:³

(1) general primary membrane stress P_m [XIII-1123(f) and (h)];

(2) local primary membrane stress P_L [XIII-1123(j)];

(3) primary bending stress P_b [XIII-1123(g) and (h)];

(4) secondary stress⁴ Q [XIII-1123(i)];

(5) peak stress F [XIII-1123(k)].

(c) Group the stress components in accordance with XIII-1130(b). Figure XIII-1141-1 is to provide assistance in assigning the stress values to the appropriate category. At any rectangular box calculate the algebraic sum of the values of σ_t which result from the different types of loadings and which have entered the box, and similarly for the other five stress components. The result is a set of six stress components in each box.

(d) Translate the stress components in the t , l , and r directions into principal stresses σ_1 , σ_2 , and σ_3 . (In many pressure vessel calculations, the t , l , and r directions may be so chosen that the shearing stress components are zero and so σ_1 , σ_2 , and σ_3 are identical to σ_t , σ_r , and σ_l .)

(e) Calculate the stress differences S_{12} , S_{23} , and S_{31} from the relations:

$$S_{12} = \sigma_1 - \sigma_2$$

$$S_{23} = \sigma_2 - \sigma_3$$

$$S_{31} = \sigma_3 - \sigma_1$$

³ See Table XIII-1130-1 and Note (4) of Fig. XIII-1141-1.

⁴ Subdivision of secondary stresses into membrane and bending components is not required because of the same stress limits apply to both components.

TABLE XIII-1130-1
CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES

Vessel Component	Location	Origin of Stress	Type of Stress	Classification
Cylindrical or spherical shell	Shell plate remote from discontinuities	Internal pressure	General membrane Gradient through plate thickness	P_m Q
		Axial thermal gradient	Membrane Bending	Q Q
	Junction with head or flange	Internal pressure	Membrane Bending	P_L Q [Note (4)]
Any shell or head	Any section across entire vessel	External load or moment, or internal pressure	General membrane averaged across full section	P_m
		External load or moment	Bending across full section	P_m
	Near nozzle or other opening	External load or moment, or internal pressure	Local membrane Bending Peak (fillet or corner)	P_L Q F
	Any location	Temperature difference between shell and head	Membrane Bending	Q Q
Dished head or conical head	Crown	Internal pressure	Membrane Bending	P_m P_b
	Knuckle or junction to shell	Internal pressure	Membrane Bending	P_L [Note (1)] Q
Flat head	Center region	Internal pressure	Membrane Bending	P_m P_b
	Junction to shell	Internal pressure	Membrane Bending	P_L P_b or Q [Note (4)]
Perforated head or shell	Typical ligament in a uniform pattern	Pressure	Membrane (averaged through cross section)	P_m
			Bending (averaged through width of ligament, but gradient through plate) Peak	P_b F
	Isolated or atypical ligament	Pressure	Membrane Bending Peak	Q F F

(Table XIII-1130-1 continues on next page)

TABLE XIII-1130-1 CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES

**TABLE XIII-1130-1 (CONT'D)
CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES**

Vessel Component	Location	Origin of Stress	Type of Stress	Classification
Nozzle (XIII-1170)	Within the limits of reinforcement defined by NC-3334	Pressure and external loads and moments, including those attributable to restrained free end displacements of the attached piping	General membrane Bending (other than gross structural discontinuity stresses) averaged through nozzle thickness	P_m P_m
		Pressure and external axial, shear, and torsional loads other than those attributable to restrained free end displacements of the attached piping	General membrane stresses	P_m
	Outside the limits of reinforcement defined by NC-3334	Pressure and external loads and moments other than those attributable to restrained free end displacements of the attached piping	Membrane Bending	P_L P_b
		Pressure and all external loads and moments	Membrane Bending Peak	P_L Q F
	Nozzle wall	Gross structural discontinuities	Local membrane Bending Peak	P_L Q F
		Differential expansion	Membrane Bending Peak	Q Q F
Cladding	Any	Differential expansion	Membrane Bending	F F
Any	Any	Radial temperature distribution [Note (3)]	Equivalent linear stress [Note (2)]	Q
			Nonlinear portion of stress distribution	F
Any	Any	Any	Stress concentration (notch effect)	F

NOTES:

- (1) Consideration shall also be given to the possibility of wrinkling and excessive deformation in vessels with a large diameter-thickness ratio.
- (2) Consider possibility of thermal stress ratchet.
- (3) Equivalent linear stress is defined as the linear stress distribution which has the same net bending moment as the actual stress distribution.
- (4) If the bending moment at the edge is required to maintain the bending stress in the middle to acceptable limits, the edge bending is classified as P_b . Otherwise, it is classified as Q .

TABLE XIII-1130-1 (CONT'D) CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES

The stress intensity S is the largest absolute value of S_{12} , S_{23} , and S_{31} .

(f) The stress intensity calculated as in (e) above from the stress components in any rectangle in Fig. XIII-1141-1 shall not exceed the allowable values of XIII-1140 which are shown in the circle adjacent to the rectangle in Fig. XIII-1141-1.

NOTE: Membrane stress intensity is derived from the stress components averaged across the thickness of the section. The averaging shall be performed at the component level, in step (b) or (c) above.

XIII-1140 BASIC STRESS INTENSITY LIMITS

XIII-1141 Five Basic Limits

The five basic stress intensity limits which are to be satisfied are given in XIII-1142 through XIII-1146 (Fig. XIII-1141-1).

XIII-1142 General Primary Membrane Stress Intensity

This is the stress intensity, derived from the average value across the thickness of a section, of the general primary stresses [XIII-1123(b)] produced by design internal pressure and other specified Design Mechanical Loads, but excluding all secondary and peak stresses. The allowable value of this stress intensity is kS_m as given in Section II, Part D, Subpart 1, Tables 2A and 2B. Values of k are given in Table NC-3217-1.

XIII-1143 Local Membrane Stress Intensity

This is the stress intensity, derived from the average value across the thickness of a section, of the local primary stresses [XIII-1123(j)] produced by Design Pressure and specified Design Mechanical Loads, but excluding all thermal and peak stresses. The allowable value of this stress intensity is $1.5kS_m$.

XIII-1144 Primary Membrane Plus Primary Bending Stress Intensity

This is the stress intensity, derived from the highest value across the thickness of a section, of the general or local primary membrane stresses plus primary bending stresses produced by Design Pressure and other specified Design Mechanical Loads, but excluding all secondary and peak stresses. For solid rectangular sections, the allowable value of this stress intensity is $1.5kS_m$. For other than solid rectangular sections, a value of α times the limit established in NC-3217 (b) may be used, where the factor α is defined as the ratio of the load set producing a fully plastic section to the load set producing initial yielding in the extreme fibers of the section. In the evaluation of the initial yield and fully plastic section capacities, the ratios of each individual load in the respective load set to each other load in that load set shall be the same as the respective ratios of the individual loads in the specified design load set. The value of α shall not exceed the value calculated for bending only ($P_m = 0$). In no case shall the value of α exceed 1.5. The propensity for buckling of the part of the section that is in compression shall be investigated. The α factor is not permitted for Level D Service Limits when inelastic component analysis is used as permitted in Appendix F.

XIII-1145 Primary Plus Secondary Stress Intensity

This is the stress intensity, derived from the highest value at any point across the thickness of a section, of the general or local primary membrane stresses plus primary bending stresses plus secondary stresses produced by specified service pressure and other specified mechanical loads and by general thermal effects. The effects of gross structural discontinuities but not of local structural discontinuities (stress concentrations) shall be included. The allowable value of this stress intensity is $3S_m$ [Note (1) of Fig. XIII-1141-1].

XIII-1146 Peak Stress Intensity

This is the stress intensity, derived from the highest value at any point across the thickness of a section, of the combination of all primary, secondary, and peak stresses produced by specified service pressures and other mechanical loads and by general and local thermal effects and including the effects of gross and local structural discontinuities. The allowable value of this stress intensity is dependent on the range of the stress difference from which it is derived and on the number of times it is to be applied. The stress intensity is to be compared with the allowable value obtained by the

methods of analysis for cyclic operation described in XIV-1200 through the use of the fatigue curves [Figs. XIV-1221.3(c)-1, XIV-1221.3(c)-2, and XIV-1221.3(c)-3].

Page 132

Page 133

NOTES

- (1) This limitation applies to the range of stress intensity. When the secondary stress is due to a temperature excursion at the point at which the stresses are being analyzed, the value of S_m shall be taken as the average of the S_m values tabulated in Section II, Part D, Subpart 1, Tables 2A and 2B for the highest and the lowest temperature of the metal during the transient. When part or all of the secondary stress is due to mechanical load, the value of S_m shall be taken as the S_m value for the highest temperature of the metal during the transient.
- (2) The stresses in category Q are those parts of the total stress which are produced by thermal gradients, structural discontinuities, etc., and do not include primary stresses which may also exist at the same point. It should be noted, however, that a detailed stress analysis frequently gives the combination of primary and secondary stresses directly and, when appropriate, this calculated value represents the total of P_m (or P_L) + P_b + Q and not Q alone. Similarly, if the stress in category F is produced by a stress concentration, the quantity F is the additional stress, produced by the notch, over and above the nominal stress. For example, if a plate has a nominal stress intensity S and has a notch with a stress concentration factor K , then $P_m = S$, $P_b = 0$, $Q = 0$, $F = P_m(K - 1)$, and the peak stress intensity equals $P_m + P_m(K - 1) = KP_m$.
- (3) S_2 is obtained from the fatigue curves [Figs. XIV-1221.3(c)-1, XIV-1221.3(c)-2, and XIV-1221.3(c)-3]. The allowable stress intensity for the full range of fluctuation is $2S_2$.
- (4) The symbols P_m , P_L , P_b , Q , and F do not represent single quantities but rather sets of six quantities representing the six stress components σ_x , σ_y , σ_z , τ_{xy} , τ_{yz} , and τ_{zx} .
- (5) Values shown are applicable when $P_L \leq 0.67S_y$. When $P_L > 0.67S_y$, use $[2.5 - 1.5(P_L/S_y)](kS_m)$. This relationship applies only to Service Level C.

FIG. XIII-1141-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY

XIII-1150 PLASTIC ANALYSIS, LIMIT ANALYSIS, AND SHAKEDOWN ANALYSIS

XIII-1151 Plastic Analysis

(a) Certain of the allowable stresses permitted in these design criteria are such that the maximum stress calculated on an elastic basis may exceed the yield strength of the material. The limit on primary plus secondary stress intensity of $3S_m$ (XIII-1145) has been placed at a level which ensures shakedown to elastic action after a few repetitions of the stress cycle except in regions containing significant local structural discontinuities or local thermal stresses. These last two factors are considered only in the performance of a fatigue evaluation.

(b) The limits on local membrane stress intensity (XIII-1143) and primary membrane plus primary bending stress intensity of $1.5kS_m$ (XIII-1144) have been placed at a level which conservatively ensures the prevention of collapse as determined by the principles of limit analysis. The following subparagraphs provide guidance in the application of plastic analysis and some relaxation of the basic stress limits which are allowed if plastic analysis is used.

XIII-1151.1 Value of Poisson's Ratio

(a) In evaluating stresses for comparison with any stress limits other than fatigue allowables, stresses shall be calculated on an elastic basis using the elastic value of Poisson's ratio.

(b) In evaluating stresses for comparison with fatigue allowables, the elastic equations shall be used, except that the numerical value substituted for Poisson's ratio shall be determined from the expression:

$$\nu = 0.5 - 0.2(S_y/S_a), \text{ but not less than } 0.3$$

where

S_y

= the yield strength, psi, of the material at the mean value of the temperature of the cycle

S_a

= the value, psi, obtained from the applicable design fatigue curve for the specified number of cycles of the condition being considered

XIII-1151.2 Plastic Analysis Procedures.

The limits on local membrane stress intensity (XIII-1143), primary plus secondary stress intensity (XIII-1145), thermal stress ratchet in shell (XIV-1410), and thermal stress in nonintegral connections (XIV-1420) need not be satisfied at a specific location if at that location the procedures of (a), (b), and (c) below are used.

(a) In evaluating stresses for comparison with the stress limits of XIII-1142, XIII-1144 (general primary membrane plus primary bending stress intensity only), XIII-1180, NC-3214.3, XIII-1160, and XIII-1121(b), the stresses are calculated on an elastic basis.

(b) In lieu of satisfying the specific requirements of XIII-1143, XIII-1145, NC-3214.3, and XIV-1420 at a specific location, the structural action is calculated on a plastic basis and the design shall be considered to be acceptable if shakedown occurs, as opposed to continuing deformation, and if the deformations which occur prior to shakedown do not exceed specified limits.

(c) In evaluating stresses for comparison with fatigue allowables, the numerically maximum principal total strain range which occurs after shakedown shall be multiplied by one-half of the modulus of elasticity of the material at the mean value of the temperature of the cycle.

XIII-1152 Limit Analysis

The limits on local membrane stress intensity (XIII-1143) and primary membrane plus primary bending stress intensity need not be satisfied at a specific location if it can be shown by means of limit analysis or by tests that the specified

mechanical and thermal loadings do not exceed two-thirds the lower bound collapse load.

XIII-1153 Shakedown Analysis

The $3S_m$ stress intensity limit on the range of primary plus secondary stress intensity (XIII-1145) may be exceeded provided that the range of primary plus secondary membrane plus bending stress intensity, excluding thermal bending stresses, shall be $\leq 3S_m$ and that the requirements of (a) through (e) below are met.

(a) The value of S_a used for entering the design fatigue curve is multiplied by the factor K_e , where

$$K_e = \begin{cases} 1.0, & \text{for } S_n < 3S_m \\ 1.0 + [(1 - n)/n(m - 1)][(S_n/3S_m) - 1], & \text{for } 3S_m < S_n < 3mS_m \\ 1/n, & \text{for } S_n \geq 3mS_m \end{cases}$$

$$S_n = \text{range of primary plus secondary stress intensity}$$

The values of the material parameters m and n are given for the various classes of permitted materials in Table XIII-1153(a)-1.

(b) The rest of the fatigue evaluation stays the same as required in Appendix XIV, except that the procedure of XIII-1151.1 need not be used.

(c) The component meets the thermal ratcheting requirement of Appendix XIV-1400.

Page 134

**TABLE XIII-1153(a)-1
VALUES OF m , n , AND $T_{\max}$ FOR VARIOUS
CLASSES OF PERMITTED MATERIALS**

Materials	m	n	$T_{\max}$, °F
Low alloy steel	2.0	0.2	700
Martensitic stainless steel	2.0	0.2	700
Carbon steel	3.0	0.2	700
Austenitic stainless steel	1.7	0.3	800
Nickel–chromium–iron	1.7	0.3	800
Nickel–copper	1.7	0.3	800

TABLE XIII-1153(a)-1 VALUES OF m , n , AND $T^{\max}$ FOR VARIOUS CLASSES OF PERMITTED MATERIALS

(d) The temperature does not exceed those listed in Table XIII-1153(a)-1 for the various classes of permitted materials.

(e) The material shall have a specified minimum yield strength to specified minimum tensile strength ratio of less than

0.80.

XIII-1160 TRIAXIAL STRESSES

The algebraic sum of the three primary principal stresses ($\sigma_1 + \sigma_2 + \sigma_3$) shall not exceed four times the tabulated value of S_m .

XIII-1170 NOZZLE PIPING TRANSITION

The P_m classification of stresses in nozzles resulting from external load or moment is applicable for that length of nozzle which lies within the limits of reinforcement whether or not nozzle reinforcement is required. Beyond the limits of reinforcement, a P_L classification may be applied to the stresses resulting from external load or moment attributable to thermal expansion of the attached piping. However, the pressure and mechanical load induced membrane stresses retain a P_m classification.

XIII-1180 BOLTING

XIII-1181 Bolt and Gasket Requirements

(a) The number and cross-sectional area of bolts required to resist internal pressure shall be determined in accordance with the procedures of Appendix XI. The allowable bolt design stresses, as used in the equations of Appendix XI, shall be the values given in Section II, Part D, Subpart 1, Table 4 for bolting materials. When sealing is effected by a seal weld instead of a gasket, the gasket factor m and the minimum design seating stress y may be taken as zero.

(b) When gaskets are used for preservice testing only, the design is satisfactory if the above requirements are satisfied for $m = y = 0$ and the requirements of XIII-1182 are satisfied when the appropriate m and y are used for the test gasket.

XIII-1182 Allowable Maximum Service Stresses in Bolts

It is recognized that actual service stresses in bolts, such as those produced by the combination of preload, pressure, and differential thermal expansion, may be higher than the values given in Section II, Part D, Subpart 1, Table 4. The maximum of such service stress, averaged across the bolt cross section and neglecting stress concentrations, shall not exceed two times the stress values of Section II, Part D, Subpart 1, Table 4. Except as restricted by XIV-1322(b), the maximum value of such service stress at the periphery of the bolt cross section resulting from direct tension plus bending and neglecting stress concentrations shall not exceed three times the stress values of Section II, Part D, Subpart 1, Table 4. Stress intensity, rather than maximum stress, shall be limited to this value when the bolts are tightened by methods other than heaters, stretchers, or other means which minimize residual torsion.

Page 135

ARTICLE XIII-2000 PRESSURE STRESSES IN OPENINGS FOR FATIGUE EVALUATION

XIII-2100 METHODS OF EVALUATION

XIII-2110 ACCEPTABLE METHODS

For the purpose of detecting peak stresses around the opening, three acceptable methods are listed in (a), (b), and (c) below.

(a) *Analytical Method.* This method uses suitable analytical techniques, such as finite element computer analyses, which provide detailed stress distributions around openings. In addition to peak stresses due to pressure, the effects of other loadings shall be included. The total peak stress at any given point shall be determined by combining stresses due to pressure, thermal, and external loadings in accordance with the rules of para. XIII-1000.

(b) *Experimental Stress Analysis.* This is based on data from experiments (para. XIII-2130).

(c) *Stress Index Method.* This uses various formulas based on data obtained from an extensive series of tests covering a range of variations of applicable dimensional ratios and configurations (para. XIII-2120). This method covers only single, isolated openings. Stress indices may also be determined by theoretical or experimental stress analysis. Such analysis may be included in the Design Report.

XIII-2120 STRESS INDEX METHOD

XIII-2121 Stress Index

The term *stress index*, as used herein, is defined as the numerical ratio of the stress components σ_p , σ_r , and σ_t under consideration to the computed membrane hoop stress in the unpenetrated vessel material. However, the material which increases the thickness of a vessel wall locally at the nozzle shall not be included in the calculations of these stress components. When the thickness of the wall is increased over that required, the values of r_1 and r_2 in Fig. XIII-2124(e)-1 shall be referred to the thickened section.

FIG. XIII-2122-1 DIRECTION OF STRESS COMPONENTS

FIG. XIII-2122-1 DIRECTION OF STRESS COMPONENTS

XIII-2122 Nomenclature

The nomenclature for the stress components are shown in Fig. XIII-2122-1 and are defined as follows:

σ_t	= the stress component in the plane of the section under consideration and parallel to the boundary of the section, psi
σ_n	= the stress component normal to the plane of the section, such as the circumferential stress around the hole in the shell, psi
σ_r	= the stress component normal to the boundary of the section, psi
S	= the stress intensity at the point under consideration, psi
R	= inside radius, in corroded condition, of cylindrical vessel, spherical vessel, or spherical head, in.

t	= nominal wall thickness less corrosion allowance, of vessel or head, in.
-----	---

**TABLE XIII-2123-1
NOZZLES IN SPHERICAL SHELLS AND
FORMED HEADS**

Stress	Inside Corner	Outside Corner
σ_n	2.0	2.0
σ_t	-0.2	2.0
σ_r	$-2t/R$	0

TABLE XIII-2123-2 NOZZLES IN CYLINDRICAL SHELLS

XIII-2123 Stress Indices for Nozzles

When the conditions of XIII-2122 are satisfied, the stress indices given in Tables XIII-2123-1 and XIII-2123-2 may be used for nozzles designed in accordance with the applicable rules of NC-3230 and NC-3259. These stress indices deal only with the maximum stresses, at certain general locations, due to internal pressure. In the evaluation of stresses in or adjacent to vessel openings and connections, it is often necessary to consider the effect of stresses due to external loadings or thermal stresses. In such cases, the total stress at a given point may be determined by superposition. In the case of combined stresses due to internal pressure and nozzle loading, the maximum stresses for a given location shall be considered as acting at the same point and added algebraically unless positive evidence is available to the contrary.

XIII-2124 Limitations of Indices of XIII-2123

The indices of XIII-2123 apply provided the conditions set forth in (a) through (g) below exist.

(a) The opening is for a circular nozzle whose axis is normal to the vessel wall. If the axis of the nozzle makes an angle ϕ with the normal to the vessel wall, an estimate of the σ_n index on the inside may be obtained from one of the following equations, provided $d/D \leq 0.15$.

For hillside connections in spheres or cylinders,

$$K_2 = K_1(1 + 2\sin^2 \phi)$$

For lateral connections in cylinders,

$$K_2 = K_1 [1 + (\tan \phi)^{4/3}]$$

where

K_1 = the σ_n inside stress index of XIII-2123 for a Radial connection

K_2 = the estimated σ_n inside stress index for the nonradial connection

(b) The arc distance measured between the center lines of adjacent nozzles along the inside surface of the shell is not less than three times the sum of their inside radii for openings in a head or along the longitudinal axis of a shell, and is not less than two times the sum of their radii for opening along the circumference of a cylindrical shell. See NC-3231.1(a)(3) when two nozzles are not on a longitudinal or circumferential line.

(c) The following dimensional ratios are met:

Ratio	Cylinder	Sphere
D/t	10 to 100	10 to 100
d/D	0.5 max	0.5 max
$d/\sqrt{Dt}$	-	0.8 max
$d/\sqrt{Dt} \sqrt{r_2/t}$	1.5 max	-

where D is the inside shell diameter, t is the shell thickness, and d is the inside nozzle diameter. In the case of cylindrical shells, the total nozzle reinforcement area on the transverse axis of the connections, including any outside of the reinforcement limits, shall not exceed 200% of that required for the longitudinal axis compared to 50% permitted by Fig. NC-3332.2-1 unless a tapered transition section is incorporated into the reinforcement and the shell, meeting the requirements of NC-3261.

(d) In the case of spherical shells and formed heads, at least 40% of the total nozzle reinforcement area shall be located beyond the outside surface of the minimum required vessel wall thickness.

(e) The inside corner radius r_1 [Fig. XIII-2124(e)-1] is between 10% and 100% of the shell thickness t .

(f) The outer corner radius r_2 [Fig. XIII-2124(e)-1] is large enough to provide a smooth transition between the nozzles and the shell. In addition, for opening diameters in cylindrical shells and 2:1 ellipsoidal heads

Page 137

greater than $1\frac{1}{2}$ shell thicknesses and in spherical shells greater than 3 shell thicknesses, the value of r_2 shall be not less than one-half the thickness of the shell or nozzle wall, whichever is greater.

FIG. XIII-2124(e)-1 NOZZLE NOMENCLATURE AND DIMENSIONS

FIG. XIII-2124(e)-1 NOZZLE NOMENCLATURE AND DIMENSIONS

(g) The radius r_3 [Fig. XIII-2124(e)-1] is not less than the greater of (1) or (2) below:

(1) $0.002\theta d_o$ where d_o is the outside diameter of the nozzle and is as shown in Fig. XIII-2124(e)-1 and the angle θ is expressed in degrees;

(2) $2(\sin \theta)^3$ times offset for the configuration shown in Fig. XIII-2124(e)-1 sketches (a) and (b).

XIII-2130 EXPERIMENTAL STRESS ANALYSIS METHOD

XIII-2131 Determination of Stress Intensities

The stress intensities for opening configurations which do not meet the requirements of NC-3230 or of XIII-2124 shall be determined in accordance with methods of Appendix II.

XIII-2132 Evaluation of Data for Similar But Slightly Different Configurations

In accordance with II-1112, reevaluation is not required for configurations for which there are available detailed experimental results that are consistent with the requirements of Appendix II. In order that available experimental data may be interpreted as providing information pertinent to the analysis of slightly different configurations, thereby possibly minimizing the need for additional investigations, the guidelines of (a) through (d) below are presented.

(a) For an unreinforced opening or for an opening where the reinforcement is provided primarily by a uniform increase in vessel wall thickness, the stresses around the opening will increase with increasing d/D

Page 138

ratio of the opening (diameter of nozzle or opening to diameter of shell). Therefore, experimental data for a small d/D ratio cannot be safely applied to a larger d/D ratio but can be applied to a smaller d/D ratio provided the experiments were made at a d/D ratio <0.5 .

(b) For an unreinforced opening or for an opening where the reinforcement is provided primarily by a uniform increase in vessel wall thickness, the stresses around the opening will increase with increasing D/t ratio for thinner shells. Therefore, experimental data for a relatively small D/t ratio cannot be safely applied to a larger D/t ratio but can be applied to a smaller D/t ratio.

(c) Generally speaking, the stress data available in the literature are applicable only to single openings. Such data should be considered valid only for a connection sufficiently removed from another nozzle, opening, flange, or other major discontinuity so that superposition of stresses will not produce an unacceptable value of stress intensity.

(d) Stresses at the outside juncture of a nozzle and shell are greatly influenced by the fillet or transition at the juncture. Generally speaking, stress data available in the literature are for certain specific fillet radii. Other factors being equal, these stress data may be considered valid for fillet radii equal to or greater than used in the test but should not be considered valid for smaller fillet radii or undefined fillets and transitions, such as for a triangular weld fillet, as commonly used.

APPENDIX XIV DESIGN BASED ON FATIGUE ANALYSIS FOR VESSELS DESIGNED IN ACCORDANCE WITH NC-3200

Page 139

ARTICLE XIV-1000 DESIGN BASED ON FATIGUE ANALYSIS

XIV-1100 INTRODUCTION

XIV-1110 SCOPE

This Appendix is applicable only to the fatigue analysis of Class 2 vessels meeting the requirements of NC-3200.

XIV-1200 ANALYSIS FOR CYCLIC SERVICE OF VESSELS

XIV-1210 GENERAL REQUIREMENTS

XIV-1211 Suitability of Vessel for Cyclic Service

The suitability of a vessel component for specified Service Conditions involving cyclic application of loads and thermal conditions shall be determined by the methods described in this Appendix, except that the suitability of high strength bolts shall be determined by the methods of XIV-1300 and the possibility of thermal stress ratchet shall be investigated in accordance with XIV-1400. If the specified service of the vessel meets all of the conditions of NC-3219, no analysis for cyclic service is required and it may be assumed that the limits on peak stress intensities as governed by fatigue have been satisfied by compliance with the applicable requirements for materials, design, fabrication, examination, and testing of Subsection NC

Subsection NC. If the service does not meet all the conditions of NC-3219, a fatigue analysis shall be made in accordance with XIV-1220 or a fatigue test shall be made in accordance with II-1150.

XIV-1212 Allowable Amplitude of Alternating Stresses

The conditions and procedures of NC-3219 and XIV-1220 are based on a comparison of peak stresses with strain cycling fatigue data. The strain cycling fatigue data are represented by the design fatigue strength curves of Figs. I-9.1, I-9.2, and I-9.3.¹ These curves show the allowable amplitude S_a of the alternating stress component (one-half of the alternating stress range) plotted against the number of cycles. The stress amplitude is calculated on the assumption of elastic behavior and hence has the dimensions of stress, but it does not represent a real stress when the elastic range is exceeded. The fatigue curves are obtained from uniaxial strain cycling data in which the imposed strains have been multiplied by the elastic modulus and a design margin has been provided, so as to make the calculated stress intensity and amplitude and the allowable stress amplitude directly comparable. The curves have been adjusted, where necessary, to include the maximum effects of mean stress, which is the condition where the stress fluctuates about a mean value which is different from zero. As a consequence of this procedure, it is essential that the requirements of XIII-1145 and XIII-1160 be satisfied at all times, with transient stresses included and that the calculated value of the alternating stress intensity be proportional to the actual strain amplitude. To evaluate the effect of alternating stresses of varying amplitudes, a linear damage relation is assumed in XIV-1220.

1 The tests on which the design curves are based did not include tests at temperatures in the creep range or in the presence of unusually corrosive environments, either of which might accelerate fatigue failure. Therefore, these curves are not applicable at service temperatures for which creep is a significant factor. In addition, the designer shall evaluate separately any effects on fatigue life which might result from an unusually corrosive environment.

XIV-1213 Loadings to Be Considered

The loadings to be considered shall include those loads that are due to testing of the vessel when such testing is in addition to that required by NC-6700.

Page 142

XIV-1220 CYCLIC LOADING

XIV-1221 Design for Cyclic Loading

XIV-1221.1 Determination of Vessel's Ability to Withstand Cyclic Loading.

If the specific service of the vessel does not meet the conditions of NC-3219, the ability of the vessel to withstand the specified cyclic service without fatigue failure shall be determined as provided herein. The determination shall be made on the basis of the stresses at a point of the vessel and the allowable stress cycles shall be adequate for the specified service at every point. Only the stresses due to the specified service cycle need be considered; stresses produced by any load or thermal condition which does not vary during the cycle need not be considered, since they are mean stresses and the maximum possible effect of mean stress is included in the fatigue design curves.

XIV-1221.2 Significance of Compliance With Requirements for Cyclic Loading.

Compliance with these requirements means only that the vessel is suitable from the standpoint of possible fatigue failure; complete suitability for the specified service is also dependent on meeting the general stress limits of XIII-1140 and any applicable special stress limits of XIV-1410.

XIV-1221.3 Cyclic Loading Design Procedure

(a) *When Principal Stress Direction Does Not Change.* For any case in which the directions of the principal stresses at the point being considered do not change during the cycle, steps (1), (2), and (3) below shall be followed to determine the alternating stress intensity:

(1) *Principal Stresses.* Consider the values of the three principal stresses at the point versus time for the complete stress cycle, taking into account both the gross and local structural discontinuities and the thermal effects which vary during the cycle. These are designated as σ_1 , σ_2 , and σ_3 for later identification.

(2) *Stress Differences.* Determine the stress differences $S_{12} = \sigma_1 - \sigma_2$, $S_{23} = \sigma_2 - \sigma_3$, and $S_{31} = \sigma_3 - \sigma_1$ versus time for the complete cycle. In what follows, the symbol S_{ij} is used to represent any one of these three stress differences.

(3) *Alternating Stress Intensity.* Determine the extremes of the range through which each stress difference S_{ij} fluctuates, and find the absolute magnitude of this range for each S_{ij} . Call this magnitude S_{rij} and let $S_{altij} = 0.5S_{rij}$. The alternating stress intensity S_{alt} is the largest of the S_{altij} values.

(b) *When Principal Stress Direction Changes.* For any case in which the directions of the principal stresses at the point being considered change during the stress cycle, it is necessary to use steps (1) through (5) below.

(1) Consider the values of the six stress components σ_p , σ_p , σ_p , τ_{lp} , τ_{lp} , and τ_{rp} versus time for the complete stress cycle, taking into account both the gross and local structural discontinuities and the thermal effects which vary during the cycle.

(2) Choose a point in time when the conditions are one of the extremes for the cycle, either maximum or minimum algebraically, and identify the stress components at this time by the subscript i . In most cases it will be possible to choose at least one time during the cycle when the conditions are known to be extreme. In some cases it may be necessary to try different points in time to find the one which results in the largest value of alternating stress intensity.

(3) Subtract each of the six stress components σ_{ip} , σ_{ip} , etc., from the corresponding stress components σ_p , σ_p , etc., at each point in time during the cycle and call the resulting components σ'_p , σ'_p , etc.

(4) At each point in time during the cycle, calculate the principal stresses σ'_1 , σ'_2 , and σ'_3 derived from the six stress components σ'_p , σ'_p , etc. Note that the directions of the principal stresses may change during the cycle but each principal stress retains its identity as it rotates.

(5) Determine the stress differences $'_{12} = \sigma'_1 - \sigma'_2$, $S'_{23} = \sigma'_2 - \sigma'_3$, and $S'_{31} = \sigma'_3 - \sigma'_1$ versus time for the complete cycle and find the largest absolute magnitude of any stress difference at any time. The alternating stress intensity S_{alt} is one-half of this magnitude.

(c) *Design Fatigue Curves.* Figures I-9.1, I-9.2.1, I-9.2.2, I-9.3, I-9.4, and I-9.5 contain the applicable fatigue design curves for some of the materials permitted by Subsection NC. When more than one curve is resented for a given material, the applicability of each curve to materials of various strength levels is identified. Linear interpolation may be used for intermediate strength levels of these materials. As used herein, the strength level is the specified minimum room temperature value.

(d) *Use of Design Fatigue Curve.* Multiply S_{alt} as determined in (a) or (b), by the ratio of the modulus of elasticity given on the design fatigue curve to the value used in the analysis. Enter the applicable design fatigue curve at this value on the ordinate axis and find the corresponding number of cycles on the abscissa. If the operational cycle being considered is the only one which produces significant fluctuating stresses, this is the allowable number of cycles.

(e) *Cumulative Damage.* If there are two or more types of stress cycles which produce significant stresses,

Page 143

their cumulative effect shall be evaluated as given in (1) through (6) below.

(1) Designate the specified number of times each type of stress cycle of types 1, 2, 3, ..., n will be repeated during the life of the vessel as n_1 , n_2 , n_3 , ..., n_n respectively. In determining n_1 , n_2 , n_3 , ..., n_n consideration shall be given to the superposition of cycles of various origins which produce a total stress difference range greater than the stress difference ranges of the individual cycles. For example, if one type of stress cycle produces 1000 cycles of a stress difference variation from 0 to +60.0 ksi and another type of stress cycle produces 10,000 cycles of a stress difference variation from 0 to -50.0 ksi, the two types of cycle to be considered are defined by the following parameters.

For type 1 cycle,

$$n_1 = 1000$$

$$S_{alt 1} = (60,000 + 50,000)/2 = 55,000 \text{ psi}$$

For type 2 cycle,

$$n_2 = 9000$$

$$S_{alt\ 2} = (50,000 + 0)/2 = 25,000 \text{ psi}$$

(2) For each type of stress cycle determine the alternating stress intensity S_{alt} by the procedures of (a) or (b) above. Call these quantities $S_{alt\ 1}, S_{alt\ 2}, S_{alt\ 3}, \dots, S_{alt\ n}$

(3) For each value $S_{alt\ 1}, S_{alt\ 2}, S_{alt\ 3}, \dots, S_{alt\ n}$ use the applicable design fatigue curve to determine the maximum number of repetitions which would be allowable if this type of cycle were the only one acting. Call these values $N_1, N_2, N_3, \dots, N_n$

(4) For each type of stress cycle, calculate the usage factors $U_1, U_2, U_3, \dots, U_n$ from $U_1 = n_1/N_1, U_2 = n_2/N_2, U_3 = n_3/N_3, \dots, U_n = n_n/N_n$

(5) Calculate the cumulative usage factor U from $U = U_1 + U_2 + U_3 + \dots + U_n$

(6) The cumulative usage factor U shall not exceed 1.0.

XIV-1222 Local Structural Discontinuities

These effects shall be evaluated for all conditions using stress concentration factors determined from theoretical, experimental, or photoelastic studies, or numerical stress analysis techniques. Experimentally determined fatigue strength reduction factors may be used when determined in accordance with the procedures of II-1600, except for high strength alloy steel bolting for which the requirements of NB-3232.2(c) shall apply when using the design fatigue curve of Fig. I-9.4. Except for the case of crack-like defects, no fatigue strength factor greater than five need be used.

XIV-1223 Fillet Welds

Fillet welds shall not be used in vessels for joints of Categories A, B, C, or D (Fig. NC-3251-1) except as permitted for joints of Category C for slip on flanges (NC-3252.3 and NC-3262.2) and for the joints of Category D as permitted in NC-3259. Fillet welds may be used for attachment to pressure vessels using one-half the stress limits of XIII-1142 through XIII-1145 for primary and secondary stresses. Evaluation for cyclic loading shall be made in accordance with Appendix XIV using a fatigue strength reduction factor of four and shall include consideration of temperature differences between the vessel and the attachment and expansion or contraction of the vessel produced by internal or external pressure.

XIV-1300 ANALYSIS FOR CYCLIC SERVICE OF BOLTS

XIV-1310 GENERAL REQUIREMENTS

XIV-1311 Suitability of Bolts for Cyclic Service

Unless the vessel on which they are installed meets all the conditions of NC-3219 and thus requires no fatigue analysis, the suitability of bolts for cyclic service shall be determined in accordance with the procedures of XIV-1320.

XIV-1320 EVALUATION OF BOLTS DEPENDENT ON THEIR MATERIAL PROPERTIES

XIV-1321 Bolts With Tensile Strengths Less Than 100 ksi (689 MPa)

Bolts made of materials which have minimum specified tensile strengths of less than 100.0 ksi (689 MPa) shall be evaluated for cyclic operation by the methods of XIV-1220, using the applicable design fatigue curve, Fig. I-9.1 or Fig. I-9.2 and an appropriate stress concentration factor (XIV-1324).

Page 144

XIV-1322 High Strength Bolts

High strength alloy steel bolts and studs may be evaluated for cyclic operation by the methods of XIV-1220, using the design fatigue curve of Fig. I-9.4, provided the requirements of (a) through (e) below are met.

(a) The material is one of the following: SA-193 Grade B-7 or B-16; SA-320 Grade L-43; SA-540 Grades B-23 and

B-24, heat treated in accordance with SA-540, Section 5.

(b) The maximum value of the service stress at the periphery of the bolt cross section resulting from direct tension plus bending and neglecting stress concentrations shall not exceed $2.7S_m$, if the higher of the two fatigue design curves given in Fig. I-9.4 is used. The $2.0S_m$ limit for direct tension is unchanged.

(c) Threads shall be of a Vee type, having a minimum thread root radius no smaller than 0.003 in. (0.076 mm).

(d) Fillet radii at the end of the shank shall be such that the ratio of fillet radius to shank diameter is not less than 0.060.

(e) The fatigue strength reduction factor used in the fatigue evaluation shall not be less than 4.0.

XIV-1323 Acceptability for Cyclic Service

The bolts shall be acceptable for the specific cyclic application of loads and thermal stresses provided the cumulative usage factor U , as determined in XIV-1221.3(e), does not exceed 1.0.

XIV-1324 Fatigue Strength Reduction Factor for Threads

Unless it can be shown by analysis or test that a lower value is appropriate, the fatigue strength reduction factor used in the fatigue evaluation of threaded members shall not be less than 4.0.

XIV-1400 ANALYSIS FOR THERMAL STRESS RATCHET

XIV-1410 THERMAL STRESS RATCHET IN SHELL

Under certain combinations of steady state and cyclic loadings there is a possibility of large distortions developing as the result of ratchet action, that is, the deformation increases by a nearly equal amount for each cycle. Examples of this phenomenon are treated in XIV-1410 and in XIV-1420.

(a) The limiting value of the maximum cyclic thermal stress permitted in a shell loaded by steady state internal pressure in order to prevent cyclic growth in diameter is as follows. Let

y' = maximum allowable thermal stress, computed on an elastic basis, divided by the yield strength² S_y

x = maximum general membrane stress due to pressure divided by the yield strength² S_y

Case 1: Linear variation of temperature through the shell wall

$$y' = 1/x \text{ for } 0 < x < 0.5$$

$$y' = 4(1 - x) \text{ for } 0.5 < x < 1.0$$

Case 2: Parabolic constantly increasing or constantly decreasing variation of temperature through the shell wall

$$y' = 5.2(1 - x) \text{ for } 0.615 < x < 1.0$$

and approximately, for $x < 0.615$, $y' = 4.65$, 3.55, and 2.70 for $x = 0.3$, 0.4, and 0.5, respectively.

(b) Use of the yield strength S_y in the above relations instead of the proportional limit allows a small amount of growth during each cycle until strain hardening raises the proportional limit to S_y . If the yield strength of the material is higher than the endurance limit³ for the material, the latter value shall be used, if there are to be a large number of cycles, because strain softening may occur.

² It is permissible to use $1.5S_m$ whenever it is greater than S_y .

³ The endurance limit shall be taken as two times the S_a value at 10^6 cycles in the applicable fatigue curve of Fig. I-9.1 or Fig. I-9.2.

XIV-1420 PROGRESSIVE DISTORTION OF NONINTEGRAL CONNECTIONS

Screwed on caps, screwed in plugs, shear ring closures, and breech lock closures are examples of nonintegral connections

Screwed on caps, screwed in plugs, shear ring closures, and breech lock closures are examples of nonintegral connections which are subject to failure by bell mouthing or other types of progressive deformation. If any combination of applied loads produces yielding, such joints are subject to ratcheting because the mating members may become loose at the end of each complete operating cycle and start the next cycle in a new relationship with each other, with or without manual manipulation. Additional distortion may occur in each cycle so that interlocking parts, such as threads, can

Page 145

eventually lose engagement. Therefore, primary plus secondary stress intensities (XIII-1145) which result in slippage between the parts of a nonintegral connection in which disengagement could occur as a result of progressive distortion shall be limited to the allowable stress limits given in XIII-1142 and XIII-1143.

APPENDIX XVIII CAPACITY CONVERSIONS FOR PRESSURE RELIEF VALVES

Page 147

ARTICLE XVIII-1000 CAPACITY CONVERSIONS FOR PRESSURE RELIEF VALVES

XVIII-1100 PROCEDURE FOR CONVERSION

XVIII-1110 EQUATIONS FOR CONVERSION (COMPRESSIBLE FLUIDS)

The capacity of a relief valve in terms of a gas or vapor other than the medium for which the valve was officially rated shall be determined by application of the following equations:¹

For dry saturated steam:

pressures up to 1500 psig

$$(1) W_s = 51.5KA P$$

1 Knowing the rated capacity of a pressure relief valve which is stamped on the valve, it is possible to determine the overall value of KA in either of the following equations in cases where the value of these individual terms is not known:

Rated Steam Capacity

For pressure up to 1500 psig

$$KA = W_s / 51.5P$$

For pressure over 1500 psig to 3200 psig

$$KA = \frac{W_s}{51.5P \left(\frac{0.1906P - 1000}{0.2292P - 1061} \right)}$$

Rated Air Capacity

$$KA = (W_s/CP) \sqrt{MT}$$

This value for KA is then substituted in the above equation to determine the capacity of the safety valve in term of the new gas or vapor.

Pressures over 1500 psig and up to 3200 psig, the value of W_s , calculated by the above equation, shall be multiplied by the following factors.

$$\frac{0.1906P - 1000}{0.2232P - 1061}$$

For superheated steam:

For superheated steam the value of W_s shall be multiplied by the appropriate superheat correction factor, K_{sh} , of Table XVIII-1110-1.

For wet saturated steam:

For wet saturated steam with a quality (dryness fraction) of 0.90 or greater, the value of W shall be corrected by dividing

by the quality of the steam used for testing.

For air:

$$(2) W_a = CKAP \sqrt{M/T}$$

where

C	= 356
M	= 28.97 mol. wt.
T	= 520 when W_a is the rated capacity

² Rated capacity (lb/hr air @ 60°F @ 14.7 psia)/0.0766 = rated capacity (scfm air).

For any gas or vapor (other than steam):

$$(3) W = CKAP \sqrt{M/T}$$

where

W_s	= rated capacity, lb/hr of steam
W_a	= rated capacity, ² converted to lb/hr of air at 60°F inlet temperature
W	= flow of any gas or vapor, lb/hr
C	= constant for gas or vapor which is a function of the ratio of specific heats, $k = c_p/c_v$ (Fig. XVIII-1110-1)

K	= coefficient of discharge
A	= actual discharge area of the pressure relief valve, sq in.
P	= (set pressure + overpressure) plus atmospheric pressure, psia
M	= molecular weight
T	= absolute temperature at inlet (°F plus 460)
Z	= ratio of deviation of the actual gas from a perfect gas, a ratio evaluated at inlet conditions

TABLE XVIII-1110-1
SUPERHEAT CORRECTION FACTOR K_{sh}

Flowing Pressure (psia)	Superheat Correction Factor K_{sh} Total Temperature, °F, of Superheated Steam

TABLE XVIII-1110-1 SUPERHEAT CORRECTION FACTOR K_{sh}

FIG. XVIII-1110-1 CONSTANT C FOR GAS OR VAPOR RELATED TO RATIO OF SPECIFIC HEATS ($k = c_p/c_v$)

FIG. XVIII-1110-1 CONSTANT C FOR GAS OR VAPOR RELATED TO RATIO OF SPECIFIC HEATS ($k = c_p/c_v$)

These equations shall also be used when the required flow of any gas or vapor is known and it is necessary to compute the rated capacity of steam or air.

(a) Molecular weight of some of the common gases and vapors are given in Table XVIII-1110(a)-1.

(b) In the case of hydrocarbons, the compressibility factor Z shall be included in the equation for gases and vapors as follows:

$$(4) W = CKAP \sqrt{M/ZT}$$

**TABLE XVIII-1110(a)-1
MOLECULAR WEIGHTS OF GASES AND VAPORS**

Gas or Vapor	Molecular Weight	Gas or Vapor	Molecular Weight
Air	28.97	Freon 22	86.48
Acetylene	26.04	Freon 114	170.90
Ammonia	17.03	Hydrogen	2.02
Butane	58.12	Hydrogen sulfide	34.08
Carbon dioxide	44.01	Methane	16.04
Chlorine	70.91	Methyl chloride	50.48
Ethane	30.07	Nitrogen	28.02
Ethylene	28.05	Oxygen	32.00
Freon 11	137.371	Propane	44.09
Freon 12	120.9	Sulfur dioxide	64.06

TABLE XVIII-1110(a)-1 MOLECULAR WEIGHTS OF GASES AND VAPOR

XVIII-1120 EXAMPLES

Example 1

Given: A pressure relief valve bears a rated capacity of 3020 lb/hr of saturated steam for a pressure setting of 200 psi.

Problem: What is the relieving capacity of that valve in terms of air at 100°F for the same pressure setting?

Page 152

Solution:

For steam:

$$W_s = 51.5KAP$$

$$3020 = 51.5KAP$$

$$KAP = 3020/51.5 = 58.6$$

For air:

$$\begin{aligned}
 W_a &= CKAP \sqrt{\frac{M}{T}} \\
 &= 356 KAP \sqrt{\frac{28.97}{460 + 100}} \\
 &= (356)(58.6) \sqrt{\frac{28.97}{560}} \\
 &= 4745 \text{ lb/hr}
 \end{aligned}$$

Example 2

Given: It is required to relieve 5000 lb/hr of propane from a pressure vessel through a pressure relief valve set to relieve at a pressure of P_s psi, and with an inlet temperature of 125°F.

Problem: What total capacity in lb/hr of steam in pressure relief valves must be furnished?

Solution:

For propane:

$$W = CKAP \sqrt{\frac{M}{T}}$$

Value of C is not definitely known. Use the conservative value, $C = 315$:

$$5000 = 315 KAP \sqrt{\frac{44.09}{460 + 125}}$$

$$KAP = 57.7$$

For steam:

W_s

$$= 51.5 KAP$$

$$= (51.5)(57.7)$$

$$= 2970 \text{ lb/hr set to relieve at } P_s, \text{ psi}$$

Example 3

Given: It is required to relieve 1000 lb/hr of ammonia from a pressure vessel at 150°F.

Problem: What is the required total capacity in lb/hr of steam at the same pressure setting?

Solution:

For ammonia:

$$W = CKAP\sqrt{M/T}$$

Manufacturer and Owner agree to use $k = 1.33$. From Fig. XVIII-1110-1, $C = 350$:

$$1000 = 350 KAP \sqrt{\frac{17.03}{460 + 150}}$$

$$KAP = 17.10$$

For steam:

$$\begin{aligned} W_s &= 51.5 KAP \\ &= (51.5)(17.10) \\ &= 880 \text{ lb/hr} \end{aligned}$$

Example 4

Given: A safety valve having a certified rating of 8000 lb/hr of steam for a pressure setting of 2000 psi.

Problem: Find the relieving capacity under the following conditions:

- (a) Steam quality (dryness fraction) of 0.93
- (b) Superheat of 100°F (total temperature of 737°F)

Solution:

The wet saturated capacity:

$$W = \frac{W_s}{0.93} = \frac{8000}{0.93}$$

$$= 8600 \text{ lb/hr}$$

The superheat capacity:

$$W = K_{sh} W_s = (0.9152)(8000)$$

$$= 7320 \text{ lb/hr}$$

NOTE: K_{sh} interpolated from Table XVIII-1110-1 for flowing conditions.

XVIII-1130 THEORETICAL FLOW

The theoretical flow for use in the establishment of the coefficient of discharge shall be calculated using Eqs. (1) through (4) of XVIII-1110 with K being deleted.

XVIII-1140 SATURATED WATER CAPACITY

(a) Because the saturated water capacity is configuration sensitive, the following applies only to those safety valves that have a nozzle type construction (throat to inlet diameter ratio of 0.25 to 0.80 with a continuously contoured change and have exhibited a coefficient K_D in excess of 0.90). No saturated water rating shall apply to other types of construction.

NOTE: The manufacturer, user, and Inspector are all cautioned that for the following rating to apply, the valve shall be continuously subjected to saturated water. If, after initial relief, the flow medium changes to quality steam, the valve shall be rated as per saturated steam. Valves installed on vessels or lines containing steam-water mixture shall be rated on saturated steam.

(b) To determine the saturated water capacity of a valve currently rated and meeting the requirements of (a) above, refer to Fig. XVIII-1140-1. Enter the graph at the set pressure of the valve, move upward to the saturated water line, and read horizontally the relieving capacity. This capacity is the theoretical, isentropic value arrived at by assuming equilibrium flow and calculated values for the critical pressure ratio.

**FIG. XVIII-1140-1 FLOW CAPACITY CURVE FOR
RATING NOZZLE TYPE SAFETY VALVES ON
SATURATED WATER (BASED ON 10%
OVERPRESSURE)**

FIG. XVIII-1140-1 FLOW CAPACITY CURVE FOR RATING NOZZLE TYPE SAFETY VALVES ON SATURATED WATER (BASED ON 10% OVERPRESSURE)

³ This conversion is not valid for liquid flashing valve operating conditions.

⁴ Knowing the rated capacity of pressure relief valve stamped with a liquid capacity, it is possible to determine the overall value of KA in the following equation where the value of the individual terms is not known:

$$KA = \frac{W_w \times 500}{2407 \sqrt{(P - 14.7)(62.3)}}$$

XVIII-1150 EQUATIONS FOR CONVERSION (INCOMPRESSIBLE FLUIDS)³

The capacity of a pressure relief valve in terms of a liquid other than the medium for which the valve was officially rated shall be determined by application of the following equation:⁴

$$W_l = 38 KA \sqrt{\frac{(P - P_d)}{G}}$$

where

W_l	= rated capacity, gpm of any liquid
W_w	= rated capacity, gpm water @ 70°F

Page 154

K	= coefficient of discharge
A	= actual discharge area of valve, sq in.
P	= (set pressure $\times$ 1.10) plus atmospheric pressure, psia
P_d	= pressure at discharge from valve, psia

G

= specific gravity of liquid⁵ ($G = 1$ for water)

XVIII-1160 EXAMPLE

Given: Pressure relief valve bearing a certified rating of 1500 gpm water @ 70°F with a set pressure of 120 psig.

⁵ Rated capacity (gpm water @ 70°F) = rated capacity (lb/hr water @ 70°F) × 1/500.

Problem: Find the flow capacity of this pressure relief valve in gpm of kerosene ($G = 0.82$) at the same pressure rating.

Solution:

For water at 70°F:

$$KA = \frac{W_w \times 500}{2407 \sqrt{(p - 14.7)(62.3)}}$$

$$KA = \frac{1500 \times 500}{2407 \sqrt{(146.7 - 14.7)(62.3)}} = 3.436$$

For kerosene:

$$W_l = 38 (3.436) \sqrt{\frac{(146.7 - 14.7)}{0.82}}$$

$$W_l = 1656.60 \text{ gpm}$$

APPENDIX XIX INTEGRAL FLAT HEAD WITH A LARGE OPENING

Page 155

ARTICLE XIX-1000 INTEGRAL FLAT HEAD WITH A LARGE OPENING

XIX-1100 GENERAL REQUIREMENTS

XIX-1110 SCOPE

(a) Rules of this Appendix apply to flat heads which have a single, circular, centrally located opening that exceeds one-half of the head diameter and have a shell/head juncture which is integrally formed or integrally attached with a full penetration weld similar to those shown in Fig. XIX-1110-1. Heads of this type shall be designed according to the rules which follow and related parts of Appendix XI.

(b) A general arrangement of an integral flat head with and without a nozzle attached at the central opening is shown in Fig. XIX-1110-2.

XIX-1120 NOMENCLATURE

(a) Except as given below, the symbols used in the equations of XIX-1200 are defined in XI-3130:

P	= internal design pressure, psi
A	= outside diameter of flat head and shell, in.
B_s	= inside diameter of shell (measured below tapered hub if one exists), in.
B_n	= diameter of central opening (for nozzle, this is inside diameter and for opening without a nozzle, diameter of the opening), in.
t	= flat head nominal thickness, in.
M_H	= moment acting at shell/head junction, in.-lb

B_p, g_p, g_r, h_p, F, V , and f are defined in XI-3130. These terms may refer to either the shell/flat head juncture or to the flat head/central opening juncture and depend upon details of those junctures.

XIX-1200 DESIGN PROCEDURE

(a) Disregard the shell attached to the outside diameter of the flat head and then analyze the flat head with a central opening (with or without nozzle) in accordance with these rules.

(1) Calculate the operating moment, M_p , according to XI-3230 (there is no M_0 for gasket seating to be considered). The formulas in Appendix XI for loads (XI-3130) and moment arms (Table XI-3230-1) shall be used directly with the following designations and terms substituted for terms in Appendix XI. Let

C	= G = inside diameter of shell B_s , in.
B	= B_n , in., where B_n is as shown in Fig. XIX-1110-2 depending on the presence of an integral nozzle or opening without a nozzle

(2) With $K = A/B_n$, use XI-3240 to calculate stresses. Designate the calculated stresses S_H^* , S_R^* , and S_T^* .

(b) Calculate $(E\theta)^*$ as follows:

(1) for integrally attached nozzle:

$$(E\theta)^* = \frac{0.91(g_1/g_0)^2 B_1 V}{fh_0} S_H^*$$

(2) for an opening without a nozzle:

$$(E\theta)^* = (B_n/t)S_T^*$$

where g_0, g_1, B_1, V, f, h_0 and B_n all pertain to the flat head/opening as described in XIX-1200(a).

(c) Calculate $(E\theta)^*/M_0$

(d) Calculate M_H :

$$M_H = \frac{(E\theta)^*}{\frac{1.74 h_0 V}{g_0^3 B_1} + \frac{(E\theta)^*}{M_0} (1 + Ft/h_0)}$$

where h_0, V, g_0, B_1 , and F refer to the shell attached to the outside diameter of the flat head.

FIG. XIX-1110-1 APPLICABLE CONFIGURATIONS OF FLAT HEADS

FIG. XIX-1110-1 APPLICABLE CONFIGURATIONS OF FLAT HEADS

FIG. XIX-1110-2 INTEGRAL FLAT HEAD WITH LARGE CENTRAL OPENING

FIG. XIX-1110-2 INTEGRAL FLAT HEAD WITH LARGE CENTRAL OPENING

(e) Calculate X_1 :

$$X_1 = \frac{M_0 - M_H (1 + Ft/h_0)}{M_0}$$

where F and h_0 refer to the shell.

(f) Calculate stresses at head/shell juncture as follows.

(1) For longitudinal hub stress in shell:

$$S_{HS} = (X_1)(E\theta) * \frac{1.10 h_0 f}{(g_1 / g_0)^2 B_s V}$$

where h_0, f, g_0, g_1, B_s , and V refer to the shell.

(2) For radial stress at outside diameter:

$$S_{RS} = \frac{1.91 M_H (1 + Ft/h_0)}{B_s t^2} + \frac{0.64 F M_H}{B_s h_0 t}$$

where B_s, F , and h_0 refer to the shell.

(3) For tangential stress at outside diameter:

$$S_{TS} = \frac{(X_1)(E\theta)^*t}{B_s} - \frac{0.57(1 + Ft/h_0)M_H}{B_s t^2} + \frac{0.64 FZ M_H}{B_s h_0 t}$$

where B_s , F , and h_0 refer to the shell, and

$$Z = \frac{K^2 + 1}{K^2 - 1}$$

(g) Calculate stresses at opening/head juncture as follows.

(1) For longitudinal hub stress in central opening:

$$S_{HO} = X_1 S_H^*$$

(2) For radial stress at central opening:

$$S_{RO} = X_1 S_R^*$$

(3) For tangential stress at diameter of central opening:

$$S_{TO} = X_1 S_T^* + \frac{0.64 F Z_1 M_H}{B_s h_0 t}$$

where F , B_s , and h_0 refer to the shell, and

$$Z_1 = \frac{2K^2}{K^2 - 1}$$

(h) The calculated stresses above shall meet the allowable stresses in XI-3250.

APPENDIX XX SUBMITTAL OF TECHNICAL INQUIRIES TO THE BOILER AND PRESSURE VESSEL COMMITTEE

Page 161

ARTICLE XX-1000 SUBMITTAL OF TECHNICAL INQUIRIES TO THE BOILER AND PRESSURE VESSEL COMMITTEE

XX-1000 INTRODUCTION

The ASME Boiler and Pressure Vessel Committee and its Subcommittees, Subgroups, and Working Groups meet regularly to consider revisions of the Code rules, new Code rules as dictated by technological development, Code Cases, and Code

interpretations. This Appendix provides guidance to Code users for submitting technical inquiries to the Committee. Technical inquiries include requests for revisions or additions to the Code rules, requests for Code Cases, and requests for Code interpretations.

Code Cases may be issued by the Committee when the need is urgent. Code Cases clarify the intent of existing Code requirements or provide alternative requirements. Code Cases are written as a question and a reply and are usually intended to be incorporated into the Code at a later date. Code interpretations provide the meaning of or the intent of existing rules in the Code and are also presented as a question and a reply. Both Code Cases and Code interpretations are published by the Committee.

The Code rules, Code Cases, and Code interpretations established by the Committee are not to be considered as approving, recommending, certifying, or endorsing any proprietary or specific design or as limiting in any way the freedom of manufacturers or constructors to choose any method of design or any form of construction that conforms to the Code rules.

As an alternative to the requirements of this Appendix, members of the Committee and its Subcommittees, Subgroups, and Working Groups may introduce requests for Code revisions or additions, Code Cases, and Code interpretations at their respective Committee meetings or may submit such requests to the secretary of a Subcommittee, Subgroup, or Working Group.

Inquiries that do not comply with the provisions of this Appendix or that do not provide sufficient information for the Committee's full understanding may result in the request being returned to the inquirer with no action.

XX-2000 INQUIRY FORMAT

Submittals to the Committee shall include:

(a) *Scope*. Specify one of the following:

- (1) Revision of present Code rule(s).
- (2) New or additional Code rule(s).
- (3) Code Case.
- (4) Code interpretation.

(b) *Background*. Provide the information needed for the Committee's Understanding of the inquiry, being sure to include reference to the applicable Code Section, Division, Edition, Addenda, paragraphs, figures, and tables. Preferably, provide a copy of the specific referenced portions of the Code.

(c) *Presentations*. The inquirer may desire or be asked to attend a meeting of the Committee to make a formal presentation or to answer questions from the Committee members with regard to the inquiry. Attendance at a Committee meeting shall be at the expense of the inquirer. The inquirer's attendance or lack of attendance at a meeting shall not be a basis for acceptance or rejection of the inquiry by the Committee.

XX-3000 CODE REVISIONS OR ADDITIONS

Requests for Code revisions or additions shall provide the following:

(a) *Proposed Revision(s) or Addition(s)*. For revisions, identify the rules of the Code that require revision and submit a copy of the appropriate rules as they appear in the Code marked up with the proposed

Page 164

revision. For additions, provide the recommended wording referenced to the existing Code rules.

(b) *Statement of Need*. Provide a brief explanation of the need for the revisions(s) or addition(s).

(c) *Background Information*. Provide background information to support the revision(s) or addition(s) including any data or changes in technology that form the basis for the request that will allow the Committee to adequately evaluate the proposed revision(s) or addition(s). Sketches, tables, figures, and graphs should be submitted as appropriate. When applicable, identify any pertinent paragraph in the Code that would be affected by the revision(s) or addition(s) and paragraphs in the Code that

reference the paragraphs that are to be revised or added.

XX-4000 CODE CASES

Requests for Code Cases shall provide a *Statement of Need* and *Background Information* similar to that defined in XX-3000 (b) and XX-3000(c), respectively, for Code revisions or additions. The proposed Code Case should identify the Code Section and Division and be written as a *Question* and a *Reply* in the same format as existing Code Cases.

XX-5000 CODE INTERPRETATIONS

Requests for Code interpretations shall provide the following:

(a) *Inquiry*. Provide a condensed and precise question, omitting superfluous background information, and, when possible, composed in such a way that a "yes" or a "no" *Reply*, possibly with brief provisos, is acceptable. The question should be technically and editorially correct.

(b) *Reply*. Provide a proposed *Reply* that will clearly and concisely answer the *Inquiry* question. Preferably, the *Reply* should be "yes" or "no" with brief provisos.

(c) *Background Information*. Provide any background information that will assist the Committee in understanding the proposed *Inquiry* and *Reply*.

XX-6000 SUBMITTALS

Submittals to and responses from the Committee shall meet the following:

(a) *Submittal*. Inquiries from Code users shall preferably be submitted in typewritten form; however, legible handwritten inquiries will also be considered. They shall include the name, address, telephone number, and a fax number, if available, of the inquirer and be mailed to the following address:

Secretary
ASME Boiler and Pressure Vessel Committee
Three Park Avenue
New York, N.Y. 10016-5990

(b) *Response*. The Secretary of the ASME Boiler and Pressure Vessel Committee or of the appropriate Subcommittee shall acknowledge receipt of each properly prepared inquiry and shall provide a written response to the inquirer upon completion of the requested action by the Code Committee.

APPENDIX XXI ADHESIVE ATTACHMENT OF NAMEPLATES

Page 165

ARTICLE XXI-1000 ADHESIVE ATTACHMENT OF NAMEPLATES

XXI-1100 INTRODUCTION

XXI-1110 SCOPE

This Appendix provides minimum requirements for the use of adhesive systems for the attachment of nameplates, limited to:

(a) the use of pressure sensitive acrylic adhesives that have been preapplied by the nameplate manufacturer to a normal thickness of at least 0.005 in. (0.13 mm) and that are protected with a moisture stable liner;

- (b) use on items with Design Temperatures within the range of -40°F to 300°F (-40°C to 149°C), inclusive;
- (c) application to clean, bare metal surfaces, with removal of antiweld spatter compound which may contain silicone;
- (d) nameplate nominal thickness not less than 0.020 in.;
- (e) use of prequalified application procedures as outlined in this Article;
- (f) use of the reapplied adhesive within an interval of 2 yr after adhesive application.

XXI-1120 NAMEPLATE APPLICATION PROCEDURE QUALIFICATION

(a) The Certificate Holder's Quality Assurance Manual shall require that written procedures, acceptable to the Authorized Inspection Agency, for the application of adhesive backed nameplates shall be prepared and qualified.

(b) The application procedure qualification shall include the following essential variable, using the adhesive and nameplate manufacturers' recommendations where applicable:

- (1) description of the pressure sensitive acrylic adhesive system employed, including generic composition;
- (2) the qualified temperature range [the cold box test temperature shall be -40°F (-40°C) for all applications];
- (3) materials of nameplate and item when the mean coefficient of expansion at design temperature of one material is less than 85% of that for the other material;
- (4) finish of the nameplate and item surfaces to which the nameplate is to be attached;
- (5) the nominal thickness and modulus of elasticity at application temperature of the nameplate when nameplate preforming is employed. A change of more than 25% in the quantity $[(\text{nameplate nominal thickness})^2 \times \text{nameplate modulus of elasticity at application temperature}]$ will require requalification;
- (6) the qualified range of preformed nameplate and companion item contour combinations when preforming is employed;
- (7) cleaning requirements for the item prior to attachment of the nameplate;
- (8) application temperature range and application pressure technique;
- (9) application steps and safeguards.

(c) Each procedure used for nameplate attachment by pressure sensitive acrylic adhesive systems shall be qualified for outdoor exposure in accordance with Standard UL-969-82, Marking and Labeling Systems, with the following additional requirements.

- (1) Width of nameplate test strip shall not be less than 1 in.
- (2) Nameplates shall have an average adhesion of not less than 8 lb/in. of width after all exposure conditions, including low temperature.
- (d) Any change in (b) above shall require requalification.
- (e) Each package of nameplates shall be identified with the adhesive application date.

**APPENDIX XXII DESIGN OF REINFORCEMENT FOR
CONE-TO-CYLINDER JUNCTION UNDER EXTERNAL
PRESSURE**

ARTICLE XXII-1000 RULES FOR REINFORCEMENT OF CONE-TO-CYLINDER JUNCTION UNDER EXTERNAL PRESSURE

XXII-1100 INTRODUCTION

XXII-1110 SCOPE

(a) The formulas of this Appendix provide for the design of reinforcement, if needed, at the cone-to-cylinder junctions for reducer sections and conical heads where all the elements have a common axis and the half-apex angle $\alpha \leq 60$ deg. Subparagraph XXII-1300(d) provides for special analysis in the design of cone-to-cylinder intersections with or without reinforcing rings where α is greater than 60 deg.

(b) In the design of reinforcement for a cone-to-cylinder juncture, the requirements of ND-3336 shall be met.

XXII-1200 NOMENCLATURE

The nomenclature given below is used in the formulas of the following subparagraphs:

A	= factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used in the stiffening ring, corresponding to the factor B , below, and the design temperature for the shell under consideration
A_e	= effective area of reinforcement due to excess metal thickness, sq in.
A_{rL}	= required area of reinforcement at large end, sq in.
A_{rS}	= required area of reinforcement at small end, sq in.
A_s	= cross-sectional area of the stiffening ring, sq in.
A_T	= equivalent area of cylinder, cone, and stiffening ring, sq in.

where

$$A_{T_L} = \frac{L_L t_s}{2} + \frac{L_c t_c}{2} + A_s, \text{ for large end}$$

$$A_{T_s} = \frac{L_s t_s}{2} + \frac{L_c t_c}{2} + A_s, \text{ for small end}$$

B	= factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used for the stiffening (see ND-3112.2)
D_L	= outside diameter of large end of conical section under consideration, in.
D_o	= outside diameter of cylindrical shell, in. (In conical shell calculations, the value of D_s and D_L should be used in calculations in place of D_o depending on whether the small end D_s , or large end D_L , is being examined.)
D_s	= outside diameter at small end of conical section under consideration, in.
E	= lowest efficiency of the longitudinal joint in the shell or head or of the joint in the reducer; $E = 1$ for butt welds in compression
E_c	= modulus of elasticity of cone material, psi
E_R	= modulus of elasticity of reinforcing material, psi
E_s	= modulus of elasticity of shell material, psi
E_x	= E_c , E_R or E_s
f_1	= axial load at large end (excluding pressure P), lb/in.
f_2	= axial load at small end (excluding pressure P), lb/in.
I_s	= required moment of inertia of the stiffening ring cross section about its neutral axis parallel to the axis of the shell, in. ⁴

I'_s

= required moment of inertia of the combined ring-shell-cone cross section about its neutral

Page 172

axis parallel to the axis of the shell, in.⁴ The width of shell which is taken as contributing to the moment of inertia of the combined section shall not be greater than $1.10 \sqrt{D_o T}$ and shall be taken as lying one-half on each side of the centroid of the ring. Portions of the shell plate shall not be considered as contributing area to more than one stiffening ring. If the stiffeners should be so located that the maximum permissible effective shell sections overlap on either or both sides of a stiffener, the effective shell section for that stiffener shall be shortened by one-half of each overlap.

$$k = \frac{S_s E_s}{S_R E_R} \text{ but not less than } 1.0$$

 L

= axial length of cone, in.

 L_c

= length of cone between stiffening rings measured along surface of cone, in. For cones without intermediate stiffeners,

$$L_c = \sqrt{L^2 + (\bar{R}_L - \bar{R}_s)^2}$$

 L_L

= design length of a vessel section, in., taken as the largest of the following: (a) the center-to-center distance between the cone-to-large-shell junction and an adjacent stiffening ring on the large shell; (b) the distance between the cone-to-large-shell junction and one-third the depth of head on the other end of the large shell if no other stiffening rings are used.

 L_s

= design length of a vessel section, in., taken as the largest of the following: (a) the center-to-center distance between the cone-to-small-shell junction and an adjacent stiffening ring on the small shell; (b) the distance between the cone-to-small-shell junction and one-third the depth of the head on the other end of the small shell if no other stiffening rings are used.

 P

= external design pressure, psi

$$Q_L = \frac{PR_L}{2} + f_1; \text{ axial compressive force at large end due to pressure and } f_1$$

$$Q_s = \frac{PR_s}{2} + f_2; \text{ axial compressive force at small end due to pressure and } f_2$$

R_L	= inside radius of large cylinder, in.
R_s	= inside radius of small cylinder, in.
S	= the lesser of twice the allowable stress at design metal temperature from Section II, Part D, Subpart 1, Tables 1A and 1B or 0.9 times the tabulated yield strength at design metal temperature from Section II, Part D, Subpart 2, Tables Y-1 and Y-2, psi
S_R	= allowable stress of reinforcing material, psi
S_s	= allowable stress of shell, psi
T	= minimum required thickness of cylinder at cone-to-cylinder junction, exclusive of corrosion allowance, in. (see ND-3133.3)
T_c	= nominal thickness of cone at cone-to-cylinder junction, exclusive of corrosion allowance, in. (see ND-3121)
T_L	= the smaller of $(T_s - T)$ or $(T_c - T_r)$, in.
T_r	= minimum required thickness of cone at cone-to-cylinder junction, exclusive of corrosion allowance, in.
T_s	= nominal thickness of cylinder at cone-to-cylinder junction, exclusive of corrosion allowance, in. (see ND-3121)
α	= one-half the included (apex) angle of the cone at the center line of the head
Δ	= value to indicate need for reinforcement at cone-to-cylinder intersection having a half-apex angle $\alpha \leq 60$ deg. When $\Delta \geq \alpha$, no reinforcement is required at the junction (see Table XXII-1200-1).

TABLE XXII-1200-1
VALUES OF Δ FOR JUNCTIONS AT THE LARGE
CYLINDER FOR $\alpha \geq 60$ deg.

$P/S E$	0	0.002	0.005	0.010	0.02
Δ , deg.	0	5	7	10	15
$P/S E$	0.04	0.08	0.10	0.125	0.15
Δ , deg.	21	29	33	37	40
$P/S E$	0.20	0.25	0.30	0.35	
Δ , deg.	47	52	57	60	Note (1)

NOTE:

(1) $\Delta = 60$ deg. for greater values of $P/S E$.

TABLE XXII-1200-1 VALUES OF Δ FOR JUNCTIONS AT THE LARGE CYLINDER FOR $\alpha \geq 60$ deg.

XXII-1300 DESIGN PRESSURE

(a) Reinforcement shall be provided at the junction of the cone with the large cylinder for conical heads and reducers without knuckles when the value of Δ obtained from Table XXII-1200-1 using the appropriate ratio $P/S E$, is less than α . Interpolation may be made in the Table.

The cross-sectional area of the reinforcement ring shall be at least equal to that indicated by the following formula:

$$A_{rL} = \frac{k Q_L R_L \tan \alpha}{S' E} \left[1 - \frac{1}{4} \left(\frac{P R_L - Q_L}{Q_L} \right) \frac{\Delta}{\alpha} \right] \quad (1)$$

(1)

When the thickness, less corrosion allowance, of both the reducer and cylinder exceeds that required by the applicable design formulas, the minimum excess thickness may be considered to contribute to the required reinforcement ring in accordance with the following formula:

$$(2) A_e = 4T_L \sqrt{R_L \bar{T}_s}$$

Any additional area of reinforcement which is required shall be situated within a distance of $\sqrt{R_L \bar{T}_s}$ from the junction of the reducer and the cylinder. The centroid of the added area shall be within a distance of $0.5 \sqrt{R_L \bar{T}_s}$ from the junction.

The reinforcement ring at the cone-to-cylinder junction shall also be considered as a stiffening ring. The required moment of inertia of a circumferential stiffening ring cross section shall not be less than that determined by the following formula:

$$I_s = \frac{AD_L^2 A_{TL}}{14.0}$$

The required moment of inertia of the combined ring-shell-core cross section shall not be less than that determined by the following formula:

$$I_s' = \frac{AD_L^2 A_{TL}}{10.9}$$

The moment of inertia for a stiffening ring at the large end shall be determined by the following procedure:

Step 1. Assuming that the shell has been designed and D_L , L_L , and T are known, select a member to be used for the stiffening ring and determine cross sectional area A . Then calculate factor B using the following formula:

$$B = \sqrt[3]{\frac{F_L D_L}{A_{TL}}}$$

where

$$F_L = PM + f_1 \tan \alpha$$

A_{TL} was defined previously.

Step 2. Enter the right-hand side of the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration at the value of B determined by Step 1. If different materials are used for the shell and stiffening ring, use the material chart resulting in the larger value of A in Step 4, below.

Step 3. Move horizontally to the left to the material/temperature line for the design metal temperature. For values of B falling below the left end of the material/temperature line, see Step 5.

Step 4. Move vertically to the bottom of the chart and read the value of A .

Step 5. For value of B falling below the left end of the material/temperature line for the design temperature, the value of A can be calculated using the formula $A = 2B/E_x$.

Step 6. Compute the value of the required moment of inertia from the formulas for I_s or I'_s above.

Step 7. Calculate the available moment of inertia of the stiffening ring using the section corresponding to that used in Step 6.

Step 8. If the required moment of inertia is greater than the moment of inertia for the section selected in Step 1, a new section with a larger moment of inertia must be selected and a new moment of inertia determined. If the required moment of inertia is smaller than the moment of inertia of the section selected in Step 1, that section is satisfactory.

The requirements of ND-4430 are to be met in attaching stiffening rings to the shell.

(b) Reinforcement shall be provided at the junction of the conical shell of a reducer without a flare and the small cylinder. The cross-sectional area of the reinforcement ring shall be at least equal to that indicated by the following formula:

$$A_{rS} = \frac{kQ_s R_s \tan \alpha}{S' E} \quad (3)$$

(3)

When the thickness, less corrosion allowance, of either the reducer or cylinder exceeds that required by the applicable design formula, the thickness may be considered to contribute to the required reinforcement ring in accordance with the following formula:

Page 174

$$A_e = \sqrt{\frac{R_s T_c}{\cos \alpha}} (T_c - T_r) + \sqrt{RT_s} (T_s - T) \quad (4)$$

(4)

Any additional area of reinforcement which is required shall be situated within a distance of $\sqrt{R_s T_s}$ from the junction, and the centroid of the added area shall be within a distance of $0.5\sqrt{R_s T_s}$ from the junction.

The reinforcement ring at the cone-to-cylinder junction shall also be considered as a stiffening ring. The required moment of

inertia of a circumferential stiffening ring cross section shall not be less than that determined by the following formula:

$$I_s = \frac{AD_s^2 A_{Ts}}{14.0}$$

The required moment of inertia of the combined ring-shell-cone cross section shall not be less than that determined by the following formula:

$$I'_s = \frac{AD_s^2 A_{Ts}}{10.9}$$

The moment of inertia for a stiffening ring at the small end shall be determined by the following procedure.

Step 1. Assuming that the shell has been designed and D_s , L_s , and T are known, select a member to be used for the stiffening ring and determine cross-sectional area A_{Ts} . Then calculate factor B using the following formula:

$$B = \frac{3}{4} \left(\frac{F_s D_s}{A_{T_s}} \right)$$

where

$$F_s = PN + f_2 \tan \alpha$$

$$N = \frac{R_s \tan \alpha}{2} + \frac{L_s}{2} + \frac{R_L^2 - R_s^2}{3R_L \tan \alpha}$$

A_{Ts} was defined previously.

Step 2. Enter the right-hand side of the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration at the value of B determined by Step 1. If different materials are used for the shell and stiffening ring, use the material chart resulting in the larger value of A in Step 4, below.

Step 3. Move horizontally to the left to the material/temperature line for the design metal temperature. For values of B falling below the left end of the material/temperature line, see Step 5.

Step 4. Move vertically to the bottom of the chart and read the value of A .

Step 5. For values of B falling below the left end of the material/temperature line for the design temperature, the value of A can be calculated using the formula $A = 2B/E_x$.

Step 6. Compute the value of the required moment of inertia from the formulas for I_s or I'_s above.

Step 7. Calculate the available moment of inertia of the stiffening ring using the section corresponding to that used in Step 6.

Step 8. If the required moment of inertia is greater than the moment of inertia for the section selected in Step 1, a new section with a larger moment of inertia must be selected and a new moment of inertia determined. If the required moment of inertia is smaller than the moment of inertia for the section selected in Step 1, that section is satisfactory.

The requirements of ND-4430 are to be met in attaching stiffening rings to the shell.

(c) Reducers, such as those made up of two or more conical frustums having different slopes, may be designed in accordance with (d) below.

(d) As an alternative to the rules provided in (a) and (b) above and when half the apex angle is greater than 60 deg., the design may be based on special analysis such as numerical methods or the beam-on-elastic-foundation analysis of Timoshenko, Hetenyi, or Watts and Lang. The stresses at the junction shall meet all of the allowable stress limits of this Division. The effect of shell and cone buckling on the required area and moment of inertia at the joint shall also be considered in the analysis. The theoretical buckling pressure of the junction shall be at least 3.3 times the allowable external design pressure of the junction.

SEC III D1 MA APP XXIII

APPENDIX XXIII QUALIFICATIONS AND DUTIES OF
SPECIALIZED PROFESSIONAL ENGINEERS

XXIII-1100 SCOPE

This Appendix presents minimum requirements for the qualification of personnel engaged in the certification activities. The personnel addressed are those who perform the following specialty fields:

(a) for Division 1:

- (1) certification of the Design Specification on behalf of the Owner;
- (2) certification of the Design Report on behalf of the N Certificate Holder;
- (3) certification of the Overpressure Protection Report on behalf of the Owner;
- (4) certification of the Load Capacity Data Sheet on behalf of the N Certificate Holder.

(b) for Division 2:

- (1) certification of the Design Specification on behalf of the Owner;
- (2) certification of the Construction Specification, Design Drawings, and Design Report on behalf of the Designer.

Also provided are the duties of these personnel in the performance of the activities described above.

XXIII-1200 QUALIFICATIONS

XXIII-1210 GENERAL

One or more Registered Professional Engineers (PE) shall be selected by the Owner, Designer, or N Certificate Holder, as applicable, to perform Code activities in the appropriate specialized fields(s), provided the qualifications of the PE in meeting the requirements of this Appendix have been evaluated and verified by the Owner, Designer, or N Certificate Holder, as applicable, responsible for the activity being certified or reviewed. Guidelines for demonstrating PE qualifications are contained in Guide C. A record of the qualifications of the PE shall be maintained by the responsible organization or the PE.

XXIII-1220 REGISTRATION AND EXPERIENCE

He shall be a Registered Professional Engineer in at least one state of the United States or Province of Canada and have the following qualifications.

He shall have 4 years of varied application experience at least 2 of which have been in each specialty field for which he performs certifying or review activities as delineated in XXIII-1230 through XXIII-1250. In addition, he shall keep current his knowledge of Code requirements and continue his professional development in his specialty field through personal study and experience, or by attendance at appropriate courses, seminars, Society meetings, and technical committee meetings. The Owner, Designer, or N Certificate Holder, as applicable, shall review the qualifications of the PE at least once every 3 years to assure that his qualifications have been maintained. A continuing record of all such activity shall be included in the qualification records of the PE.

XXIII-1230 CERTIFIER OF THE DESIGN SPECIFICATION

To qualify as certifier of the Design Specification on behalf of the Owner, the PE shall be experienced in the applicable field of design and related nuclear power plant requirements, and in the application of the requirements of the Code relating to the construction of nuclear power plant items. This experience shall indicate that the PE has sufficient knowledge of anticipated plant and system operating and test conditions and their relationship to Code design criteria pertinent to the applicable Code item. In addition, he shall

be knowledgeable of the specific Code requirements pertaining to his specialty field. Guidelines reflecting the degree of knowledge appropriate for preparation of the Design Specification are contained in Guide B, Table B1.

knowledge appropriate for preparation of the Design Specification are contained in Guide B, Table B1.

XXIII-1240 CERTIFIER OF THE LOAD CAPACITY DATA SHEET, CONSTRUCTION SPECIFICATION, DESIGN DRAWINGS, AND DESIGN REPORT

To qualify as certifier of the Load Capacity Data Sheet, the Construction Specification, Design Drawings, or Design Report, the PE shall be experienced in the applicable field of design and analysis and in the application of the requirements of the Code. In addition, he shall be knowledgeable of the specific Code requirements pertaining to his specialty field. Guidelines reflecting the degree of knowledge appropriate for preparation of the Design Report (Division 1), the Load Capacity Data Sheet, and the Construction Specification, Design Drawings, and Design Report (Division 2) are contained in Guide B, Tables B2, B4, and B5, respectively.

XXIII-1250 CERTIFIER OF THE OVERPRESSURE PROTECTION REPORT

To qualify as certifier of the Overpressure Protection Report on behalf of the Owner, the PE shall be experienced in nuclear power plant systems design, and in plant operation and safety control. In addition, he shall be knowledgeable of the specific Code requirements pertaining to his specialty field. Guidelines reflecting the degree of knowledge appropriate for preparation of the Report on Overpressure Protection are contained in Guide B, Table B3.

XXIII-1300 DUTIES

XXIII-1310 GENERAL

The certification activities covered in this Appendix may be performed only if the PE has assured himself that he is qualified to do so by virtue of a self-review establishing that his qualifications meet those required by this Appendix. He shall be familiar with the Quality Assurance requirements of the organization responsible for providing the document as these requirements relate to his work. For certification activities, the document being certified must have been reviewed in detail by the certifying PE, or prepared by him or prepared under his responsible direction. He shall prepare a statement¹ to be affixed to the document attesting to compliance with the applicable requirements of the Code.

XXIII-1320 CERTIFICATION OF THE DESIGN SPECIFICATION

It is the responsibility of the PE certifying the Owner's Design Specification to assure that the Design Specification is correct, complete, and in compliance with the requirements of the applicable Edition and Addenda of the Code. As a minimum, the certifier of the Design Specification shall assure that:

- (a) the function of the item is properly specified;
- (b) the design requirements, including identification of the item Design and Service Loadings and their combinations and associated Limits, are properly specified;
- (c) the proper environmental conditions, including corrosion, erosion, and radiation, are specified;
- (d) the Code classification is properly specified;
- (e) the definition of the specific boundaries and load conditions on these boundaries for each item is specified, and that the boundaries and associated load conditions between adjacent components and structure are compatible with the overall system design;
- (f) the specified materials for items covered by the Code are permitted by the Code for the applicable item;
- (g) all requirements with regard to impact testing are specified;
- (h) any restrictions on or additional requirements for heat treating are specified;
- (i) any restrictions on cladding materials are specified;
- (j) any reduction to design stress intensity values, allowable stress, or fatigue curves necessitated by the given environmental conditions are specified;
- (k) the necessary information concerning the load is given carrying capacity of structures supporting Code items;

(l) when operability of a component is a requirement, the Design Specification shall make reference to other appropriate documents that specify the operating requirements;

(m) the overpressure protection requirements are specified;

1 Illustrative samples of statements are shown in Guide A.

Page 179

(n) the Code Edition, Addenda, and Code Cases to be used for construction are specified.

XXIII-1330 CERTIFICATION OF THE DIVISION 1 DESIGN REPORT

It is the responsibility of the PE certifying the Division 1 Design Report to assure that the design of the item complies with the requirements of the applicable Edition and Addenda of the Code for the Design, Service, and Test Loadings that have been specified in the Design Specification. As a minimum, the certifier of the Design Report shall assure that:

(a) the Design Report reflects the design as shown by the drawings used for construction and that all modifications to the drawings and construction deviations have been reconciled with the Design Report;

(b) the design as shown by the drawings is in accordance with the requirements of the Code;

(c) the Design Report is in accordance with the requirements of the Code;

(d) materials specified for Code items are permitted by the Code, and that any reduction of material impact properties from heat treatments, welding, and forming have been taken into account;

(e) the Design Report is based on the Design, Service, and Test Loadings stated in the Design Specification;

(f) the specified requirements for protection against nonductile fracture are specified;

(g) all special nondestructive examinations required to validate unique features have been specified in appropriate documents/drawings;

(h) the specified test pressure and temperature are in compliance with Code requirements;

(i) adequate analytical techniques have been employed to assess the structural adequacy of the item of concern for the Design, Service, and Test Loadings specified.

XXIII-1340 CERTIFICATION OF THE OVERPRESSURE PROTECTION REPORT

It is the responsibility of the PE certifying the Overpressure Protection Report to assure that the report has been reconciled with the system requirements and with the requirements of the applicable Subsection of the Code.

XXIII-1350 CERTIFICATION OF THE LOAD CAPACITY DATA SHEET

It is the responsibility of the PE certifying the Load Capacity Data Sheet on behalf of the N Certificate Holder to determine that the load capacity of the component or piping support is rated in accordance with Subsection NF of the Code. He shall assure that the design of the component or piping support complies with the requirements of the applicable Edition and Addenda of the Code for the Design, Service, and Test Loadings specified in the Design Specification. In addition, his duties shall include the requirements of XXIII-1330(a) through (i) for the data substantiating the Load Capacity Data Sheet.

XXIII-1360 CERTIFICATION OF THE CONSTRUCTION SPECIFICATION DESIGN DRAWINGS, OR DESIGN REPORT FOR DIVISION 2

It is the responsibility of the PE certifying the Construction Specification, Design Drawings, or Design Report on behalf of the Designer for Division 2 to assure that each of the above principal Code documents is correct, complete, and in accordance with the Design Specification and Section III, Division 2. As a minimum, the certifier of each of the principal Code documents shall assure:

(a) that the Design Drawings contain:

(1) concrete and steel liner thicknesses;

(2) size and location of reinforcing steel, prestressing tendons, and penetrations;

(3) the latest revisions to reflect any change in design.

(b) that the Design Report includes the requirements of XXIII-1330(a) through (i), as applicable.

(c) that the Construction Specification has provided the following in accordance with the Code:

(1) material specifications;

(2) material shipping, handling, and storage requirements;

(3) requirements for personnel or equipment qualification;

(4) material or part examination and testing requirements;

(5) acceptance and leakage testing requirements;

(6) requirements for shop drawings;

(7) requirements for batching, mixing, placing, and curing of concrete;

(8) requirements for the fabrication and installation of the prestressing system, reinforcing steel, and embedments;

Page 180

(9) identification of parts requiring a Code stamp;

(10) design life for parts and materials where necessary to establish compliance with the Design Specification;

(11) construction surveillance to be performed by the Designer as required by the Design Specification;

(12) the latest revisions to reflect any change in design.

GUIDE B - NONMANDATORY GUIDELINES FOR ESTABLISHING ASME CODE KNOWLEDGE

This Guide provides guidelines for establishing the degree of Code knowledge required by the certifying PE in his specialty field. In the paragraphs that follow, the degree of knowledge required by the PE of the requirements of the Code pertaining to his specialty field is indicated by the terminology "general knowledge" and "working knowledge."

As used in this Guide, "general knowledge" signifies having sufficient acquaintance with the Code to be conversant with other persons involved in its applications, and to make prudent judgements in the application of Code requirements.

As used in this Guide, "working knowledge" signifies understanding by prior customary involvement in a specialty field of the Code requirements and of the principles on which the Code rules are based, to the extent that the PE may apply or direct others in the application of the requirements.

In this sense, "working knowledge" implies a more thorough understanding of the Code requirements and the ability to apply them than does "general knowledge" of the Code.

The degree of knowledge in the various areas of the Code cited in Tables B1 through B5 is based upon the more common Code items and activities. There may be special items or activities for which the degree of knowledge in a specific Code area must be more detailed than shown in the applicable table, or may require knowledge of specific Code areas that are not cited.

In the following tables, the degree of knowledge required by the PE of the various requirements of the Code pertinent to his specialty field is indicated by the letter G for "general knowledge" and the letter W for "working knowledge."

Guide C - NONMANDATORY GUIDELINES FOR DEMONSTRATING PE QUALIFICATIONS

This Guide provides suggested methods for demonstrating that the requirements for the qualification of personnel engaged in certification activities have been met. The Owner, Designer, or N Certificate Holder, as applicable, responsible for the activity being certified should establish procedures or instructions for evaluating, verifying, and documenting the qualifications of the PE engaged in certifying activities as required by this Appendix

The PE's qualifications for the requirements of XXIII-1220 may be demonstrated as follows.

(a) PE registration in one or more states of the United States or provinces of Canada should be documented on records that, as a minimum, include:

- (1) PE's identification
- (2) state or province of registration
- (3) registration number
- (4) expiration date

(b) The 4 years of varied application experience, including 2 years in his specialty field(s), should be documented in a resume describing the PE's Code experience and places and dates of employment.

(c) In order for the PE to keep current his knowledge of the Code requirements and to continue his professional development in his specialty field(s), as required by this Appendix, he should, in the 36-month period preceding the date of qualification, have performed Code activities requiring certification in his specialty field(s), or have been engaged in the application of Code requirements to an equivalent extent, but not necessarily including Certification. Alternatively, he should have done two or

more of the following:

- (1) taught or attended an appropriate course or training program;
 - (2) taught or attended an appropriate seminar;
 - (3) attended an ASME or ASME/ACI Code meeting;
 - (4) attended a technical society meeting related to his specialty field.
- (d) The PE's participation in these activities should be documented in appropriate records that, as a minimum, include:
- (1) PE's identification
 - (2) description of Code activities performed
 - (3) course or training program description, duration, and date completed
 - (4) seminar description, duration, and date attended
 - (5) ASME or ASME/ACI Code meeting(s) and date(s) attended
 - (6) technical society meeting(s) and date(s) attended
 - (7) the PE's function (i.e., attendee, member, speaker, chairman, etc.) indicating the nature of his participation.

Guide B provides guidance regarding knowledge of the Code that the PE should have in each specialty field. The PE's qualifications regarding knowledge of the Code may be demonstrated by any one of the following methods:

(e) The Owner, Designer, or N Certificate Holder, as applicable, upon review of the experience record of the PE, declares in writing that (1) the PE's knowledge of the Code in his specialty field meets the requirements, and (2) the PE's experience record reflects successful performance of the applicable Code activities in connection with the construction of ASME Code items.

(f) Another PE previously qualified to this Appendix, designated by the Owner, Designer, or N Certificate Holder, as applicable, and familiar with the requirements of the Code, after reviewing the qualifications of the PE to be qualified, attests in writing that the PE's knowledge of the Code in his specialty field(s) meets the requirements of this Appendix.

(g) Attendance of the PE at appropriate courses or seminars that provide instruction in the Code for his specialty field(s) to import knowledge of the Code required by this Appendix. Training should be scheduled as required by this Appendix, at a frequency consistent with significant changes to the Code in his specialty field(s). Training may be accomplished by attending in-house courses or courses presented by others. Training should be documented on appropriate records that, as a minimum, include:

- (1) attendee's identification
- (2) instructor's name and affiliation
- (3) outline or description of course or seminar
- (4) date and duration of course or seminar

(h) Examination of the PE in his specialty field(s), either written or oral, to verify his knowledge of the Code as required by this Appendix. The examination may be developed and/or administered either in-house

Page 190

or by others. Examinations should be documented on appropriate records that, as a minimum, include:

- (1) attendee's identification
- (2) examiner's name and affiliation
- (3) outline or description of examination
- (4) date and results of the examination

NONMANDATORY

APPENDICES

Page 193

ARTICLE A-1000 STRESS ANALYSIS METHODS

A-1100 INTRODUCTION

A-1110 SCOPE

(a) The Articles of this Appendix illustrate some acceptable methods of analysis to determine the stresses and stress intensities required to ensure the adequacy of a design as defined in NB-3200.

(b) The methods presented here are not intended to exclude others such as computer programs working directly with shell equations or finite element breakdowns of the component under investigation.

Page 200

ARTICLE A-2000 ANALYSIS OF CYLINDRICAL SHELLS

A-2100 INTRODUCTION

A-2110 SCOPE

(a) In this Article equations are given for stress and deformations in cylindrical shells subjected to internal pressure only. Refer to NB-3133.3 for cylindrical shells subjected to external pressure.

(b) Equations are given for bending analysis for uniformly distributed edge loads.

A-2120 SIGN CONVENTION AND NOMENCLATURE

The sign convention arbitrarily chosen for the analysis of cylindrical shells in this Article is as indicated in Fig. A-2120-1. Positive directions assumed for pertinent quantities are indicated.

The symbols and sign convention adopted in this Article for the analysis of cylindrical shells are defined as follows:

D	$= Et^3/12(1 - \nu^2)$, in.-lb
E	= modulus of elasticity, psi
L	= length cylinder, in., used as subscript to denote evaluation of a quantity at end of cylinder removed from reference end
M	= longitudinal bending moment per unit length of circumference, in.-lb/in.
o	= used as subscript to denote evaluation of a quantity at reference end of cylinder, $x = 0$

p	= internal pressure, psi
Q	= radial shearing forces per unit length of circumference, lb/in.
R	= inside radius, in.
S	= stress intensity, psi
t	= thickness of cylinder, in.
w	= radial displacement of cylinder wall, in.
x	= axial distance measured from the reference end of cylinder, in.
Y	= ratio of outside radius to inside radius
Z	= ratio of outside radius to an intermediate radius
β	= $[3(1 - \nu^2)/(R + t/2)^2 t]^{\frac{1}{4}}$, in. ⁻¹
θ	= rotation of cylinder wall, rad
	= dw/dx
ν	= Poisson's ratio
σ_t	= tangential (circumferential) stress component, psi
σ_l	= longitudinal (meridional) stress component, psi
σ_r	= radial stress component, psi
$F_{11}(\beta x)$	= $(\cosh \beta x \sin \beta x - \sinh \beta x \cos \beta x)/2$
$F_{12}(\beta x)$	= $\sinh \beta x \sin \beta x$
$F_{13}(\beta x)$	= $(\cosh \beta x \sin \beta x + \sinh \beta x \cos \beta x)/2$
$F_{14}(\beta x)$	= $\cosh \beta x \cos \beta x$
$f_1(\beta x)$	= $e^{-\beta x} \cos \beta x$
$f_2(\beta x)$	= $e^{-\beta x} (\cos \beta x - \sin \beta x)$

Page 201

$f_3(\beta x)$	= $e^{-\beta x} (\cos \beta x + \sin \beta x)$
$f_4(\beta x)$	= $e^{-\beta x} \sin \beta x$
B_{11}	= $B_{11}(\beta L)$ = $(\sinh 2\beta L - \sin 2\beta L)/2(\sinh^2 \beta L - \sin^2 \beta L)$
B_{12}	= $B_{12}(\beta L)$ = $(\cosh 2\beta L - \cos 2\beta L)/2(\sinh^2 \beta L - \sin^2 \beta L)$
B_{22}	= $B_{22}(\beta L)$ = $(\sinh 2\beta L + \sin 2\beta L)/2(\sinh^2 \beta L - \sin^2 \beta L)$
G_{11}	= $G_{11}(\beta L)$

G_{12}

G_{22}

$$= -(\cosh \beta L \sin \beta L - \sinh \beta L \cos \beta L)/(\sinh^2 \beta L - \sin^2 \beta L)$$

$$= G_{12}(\beta L)$$

$$= -2 \sinh \beta L \sin \beta L/(\sinh^2 \beta L - \sin^2 \beta L)$$

$$= G_{22}(\beta L)$$

$$= -2(\cosh \beta L \sin \beta L + \sinh \beta L \cos \beta L)/(\sinh^2 \beta L - \sin^2 \beta L)$$

FIG. A-2120-1

A-2200 STRESS INTENSITIES, DISPLACEMENTS, BENDING MOMENTS, AND LIMITING VALUES

A-2210 PRINCIPAL STRESSES AND STRESS INTENSITIES DUE TO INTERNAL PRESSURE

A-2211 Loading Effects Considered

In this Subarticle equations are given for principal stresses and stress intensities resulting from uniformly distributed internal pressure in cylindrical shells. The effects of discontinuities in geometry and loading are not included and should be evaluated independently. The stresses resulting from all effects shall be combined by superposition.

A-2212 Principal Stresses

The principal stresses developed at any point in the wall of a cylindrical shell due to internal pressure are given by the following equations:

$$(1) \sigma_1 = \sigma_t = p(1 + Z^2)/(Y^2 - 1)$$

$$(2) \sigma_2 = \sigma_l = p/(Y^2 - 1)$$

$$(3) \sigma_3 = \sigma_r = p(1 - Z^2)/(Y^2 - 1)$$

A-2220 STRESS INTENSITIES

A-2221 General Primary Membrane Stress Intensity

The general primary membrane stress intensity developed in a cylindrical shell as a result of internal pressure is given by the equation:

$$(4) S = (pR/t) + (p/2)$$

A-2222 Maximum Value of Primary Plus Secondary Stress Intensity

The maximum value of the primary plus secondary stress intensity in a cylindrical shell as a result of internal pressure occurs at the inside surface and is given by the equation:

$$(5) S = 2pY^2/(Y^2 - 1)$$

[98]

A-2223 Values of Radial Stress Used

Note that in evaluating the general primary membrane stress intensity, the average value of the radial stress has been taken as $p/2$. This has been done to obtain a result consistent with burst pressure analyses. On the other hand, the radial stress value used in A-2212 is p , the value at the inner surface, since the purpose of that quantity is to control local behavior.

[98]

A-2230 BENDING ANALYSIS FOR UNIFORMLY DISTRIBUTED EDGE LOADS

A-2231 Behavior of Shells Subjected to Bending Moments

The equations in this Subarticle describe the behavior of cylindrical shells when subjected to the action of bending moments M , in.-lb/in. of circumference, and radial shearing forces Q , lb/in. of circumference, uniformly distributed at the edges and acting at the mean radius of the shell. The behavior of shells due to all other loadings must be evaluated independently and combined by superposition.

A-2240 DISPLACEMENTS, BENDING MOMENTS, AND SHEARING FORCES IN TERMS OF CONDITIONS AT REFERENCE EDGE ($x = 0$)

A-2241 Equations for Conditions of Any Axial Location

The radial displacement $w(x)$, the angular displacement or rotation $\theta(x)$, the bending moments $M(x)$, and the radial shearing forces $Q(x)$ at any axial location of the cylinder are given by the following equations in terms of w_o , θ_o , M_o , and Q_o .

$$w(x) = (Q_o/2\beta^3 D)F_{11}(\beta x) + (M_o/2\beta^2 D)F_{12}(\beta x) + (\theta_o/\beta)F_{13}(\beta x) + w_o F_{14}(\beta x) \quad (6)$$

$$\begin{aligned} \theta(x)/\beta &= (Q_o/2\beta^3 D)F_{12}(\beta x) \\ &+ 2(M_o/2\beta^2 D)F_{13}(\beta x) \\ &+ (\theta_o/\beta)F_{14}(\beta x) - 2w_o F_{11}(\beta x) \end{aligned} \quad (7)$$

$$\begin{aligned} M(x)/2\beta^2 D &= (Q_o/2\beta^3 D)F_{13}(\beta x) \\ &+ (M_o/2\beta^2 D)F_{14}(\beta x) \\ &- (\theta_o/\beta)F_{11}(\beta x) - w_o F_{12}(\beta x) \end{aligned} \quad (8)$$

$$\begin{aligned} Q(x)/2\beta^3 D &= (Q_o/2\beta^3 D)F_{14}(\beta x) \\ &- 2(M_o/2\beta^2 D)F_{11}(\beta x) \\ &- (\theta_o/\beta)F_{12}(\beta x) - 2w_o F_{13}(\beta x) \end{aligned} \quad (9)$$

(6 - 9)

[98]

A-2242 Equations When Cylinder Length $\geq 3/\beta$

In the case of cylinders of sufficient length, the equations in A-2241 reduce to those given below. These equations may be used for cylinders characterized by lengths not less than $3/\beta$. The combined effects of loadings at the two edges may be evaluated by applying the equations to the loadings at each edge, separately, and superposing the results.

$$\begin{aligned} w(x) = & (Q_o/2\beta^3 D)f_1(\beta x) \\ & + (M_o/2\beta^2 D)f_2(\beta x) \end{aligned} \quad (10)$$

(10)

$$\begin{aligned} \theta(x)/\beta = & - (Q_o/2\beta^3 D)f_3(\beta x) \\ & - 2(M_o/2\beta^2 D)f_1(\beta x) \end{aligned} \quad (11)$$

$$\begin{aligned} M(x)/2\beta^2 D = & (Q_o/2\beta^3 D)f_4(\beta x) \\ & + (M_o/2\beta^2 D)f_3(\beta x) \end{aligned} \quad (12)$$

$$\begin{aligned} Q(x)/2\beta^3 D = & (Q_o/2\beta^3 D)f_2(\beta x) \\ & - 2(M_o/2\beta^2 D)f_4(\beta x) \end{aligned} \quad (13)$$

(11 - 13)

[98]

A-2243 Edge Displacements and Rotations in Terms of Edge Loads

The radial displacement w_o and w_L and rotations θ_o and $-\theta_L$, developed at the edges of a cylindrical shell sustaining the action of edge loads Q_o , M_o , Q_L , and M_L , are given by the following equations:

$$\begin{aligned} w_o = & (B_{11}/2\beta^3 D)Q_o + (B_{12}/2\beta^2 D)M_o \\ & + (G_{11}/2\beta^3 D)Q_L + (G_{12}/2\beta^2 D)M_L \end{aligned} \quad (14)$$

$$\begin{aligned} -\theta_o = & (B_{12}/2\beta^2 D)Q_o + (B_{22}/\beta D)M_o \\ & + (G_{12}/2\beta^2 D)Q_L + (G_{22}/2\beta D)M_L \end{aligned} \quad (15)$$

$$\begin{aligned} w_L = & (G_{11}/2\beta^3 D)Q_o + (G_{12}/2\beta^2 D)M_o \\ & + (B_{11}/2\beta^3 D)Q_L + (B_{12}/2\beta^2 D)M_L \end{aligned} \quad (16)$$

$$\begin{aligned} \theta_L = & (G_{12}/2\beta^2 D)Q_o + (G_{22}/2\beta D)M_o \\ & + (B_{12}/2\beta^2 D)Q_L + (B_{22}/\beta D)M_L \end{aligned} \quad (17)$$

(14 - 17)

A-2250 LIMITING VALUE OF FUNCTIONS

A-2251 General Limiting Values of Influence Functions

The influence functions B and G , appearing in the equations in A-2243, rapidly approach limiting values as the length L of the cylinder increases. The limiting values are

Page 203

$$B_{11} = B_{12} = B_{22} = 1$$

$$G_{11} = G_{12} = G_{22} = 0$$

(a) Thus, for cylindrical shells of sufficient length, the loading conditions prescribed at one edge do not influence the displacements at the other edge.

(b) In the case of cylindrical shells characterized by lengths not less than $3/\beta$, the influence functions B and G , are sufficiently close to the limiting values so that the limiting values may be used in the equations in A-2243 without significant error.

A-2252 Limiting Values of Influence Functions for Short Cylinders

In the case of sufficiently short cylinders, the influence functions B and G , appearing in the equations in A-2243, are, to a first approximation, given by the following expressions:

$$B_{11} = 2/\beta L$$

$$B_{12} = 3/(\beta L)^2$$

$$B_{22} = 3/(\beta L)^3$$

$$G_{11} = -1/\beta L$$

$$G_{12} = -3/(\beta L)^2$$

$$G_{22} = -6/(\beta L)^3$$

Introducing these expressions for the influence functions B and G into the equations in A-2243 yields expressions identical to those obtained by the application of ring theory. Accordingly, the resultant expressions are subject to all of the limitations inherent in the ring theory, including the limitations due to the assumption that the entire cross-sectional area of the ring $t \times L$ rotates about its centroid without distortion. Nevertheless, in the analysis of very short cylindrical shells characterized by lengths not greater than $1/2\beta$, the expressions may be used without introducing significant error.

A-2260 PRINCIPAL STRESSES DUE TO BENDING

The principal stresses developed at the surfaces of a cylindrical shell at any axial location x due to uniformly distributed edge loads (Fig. A-2120-1) are given by the equations:

$$(18) \sigma_1 = \sigma_t(x) = Ew(x)/(R + t/2) \pm 6vM(x)/t^2$$

$$(19) \sigma_2 = \sigma_l(x) = \pm 6M(x)/t^2$$

$$(20) \sigma_3 = \sigma_r = 0$$

In these equations, where terms are preceded by a double sign $\pm$, the upper sign refers to the inside surface of the cylinder and the lower sign refers to the outside surface.

Page 204

ARTICLE A-3000 ANALYSIS OF SPHERICAL SHELLS

A-3100 INTRODUCTION

A-3110 SCOPE

(a) In this Article equations are given for stresses and deformations in spherical shells subjected to internal or external pressure.

(b) Equations are also given for bending analysis of partial spherical shells under the action of uniformly distributed edge forces and moments.

A-3120 NOMENCLATURE AND SIGN CONVENTION

(a) The symbols and sign convention adopted in this Article are defined as follows:

p	= uniform pressure internal or external, psi
M	= meridional bending moment per unit length of circumference, in.-lb/in.
H	= force per unit length of circumference, perpendicular to center line of sphere, lb/in.
N	= membrane force, lb/in.
Q	= radial shearing force per unit of circumference, lb/in.
S	= stress intensity, psi
R_m	= radius of midsurface of spherical shell, in.
R	= inside radius, in.
t	= thickness of spherical shell, in.
E	= modulus of elasticity, psi
ν	= Poisson's ratio
D	= $Et^3/12(1 - \nu^2)$, flexural rigidity, in.-lb

$$\beta = [3(1 - \nu^2)/R_m^2 t^2]^{1/4}, \text{ in.}^{-1}$$

TERM

ϕ	= meridional angle measured from center line of sphere, deg.
ϕ_o	= meridional angle of reference edge where loading is applied, deg.
ϕ_L	= meridional angle of second edge, deg.
α	= meridional angle measured from the reference edge, rad
x	= length of arc, in., for angle α , measured from reference edge of hemisphere

	$= \pi R_m \alpha / 180$
λ	$= \beta R_m$
Y	$=$ ratio of outside radius to inside radius
Z	$=$ ratio of outside radius to an intermediate radius
U	$=$ ratio of inside radius to an intermediate radius
w	$=$ radial displacement of midsurface, in.
δ	$=$ lateral displacement of midsurface, perpendicular to center line of spherical shell, in.
θ	$=$ rotation of midsurface, rad
o	$=$ used as a subscript to denote a quantity at the reference edge of sphere
l	$=$ used as a subscript to denote meridional direction
t	$=$ used as a subscript to denote circumferential direction
K_1	$= 1 - [(1 - 2\nu)/2\lambda] \cot(\phi_o - \alpha)$
K_2	$= 1 - [(1 + 2\nu)/2\lambda] \cot(\phi_o - \alpha)$
k_1	$= 1 - [(1 - 2\nu)/2\lambda] \cot \phi_o$
k_2	$= 1 - [(1 + 2\nu)/2\lambda] \cot \phi_o$
A_o	$= \sqrt{1 + k_1^2}$
$B(\alpha)$	$= [(1 + \nu^2)(K_1 + K_2) - 2K_2]$
$C(\alpha)$	$= \sqrt{\sin \bar{\phi}_o / \sin(\bar{\phi} - \bar{\alpha})}$
$F(\alpha)$	$= \sqrt{\sin \bar{\phi}_o / \sin(\bar{\phi} - \bar{\alpha})}$
γ_o	$= \tan^{-1}(-k_1)$
σ_r	$=$ radial stress component, psi
σ_t	$=$ tangential (circumferential) stress component, psi
σ_l	$=$ longitudinal (meridional) stress component, psi

(b) The sign convention is listed below and shown in Fig. A-3120-1 by the positive directions of the pertinent quantities:

(p) pressure, positive radially outward

(δ) lateral displacement, perpendicular to λ of sphere, positive outward

(θ) rotation, positive when accompanied by an increase in the radius or curvature, as caused by a positive moment

(M), (M_o) moment, positive when causing tension on the inside surface

(H), (H_o) force perpendicular to λ , positive outward

(a) Spherical Segment, for Values of ϕ_0 :
 $162/\lambda \leq \phi_0 \leq 180 \text{ deg.} - 162/\lambda$

(b) Hemisphere for $\phi_0 = 90 \text{ deg.}$

(c) Frustum, for Values of ϕ_0 :
 $\phi_0 \leq 180 \text{ deg.} - 162/\lambda$ and $|\phi_0 - \phi_e| \geq 160/\lambda$

FIG. A-3120-1

FIG. A-3120-1

(N_p), (N_t) membrane force, positive when causing tension

A-3200 STRESS INTENSITIES, BENDING ANALYSIS, DISPLACEMENTS, AND EDGE LOADS

A-3210 PRINCIPAL STRESSES AND STRESS INTENSITIES RESULTING FROM INTERNAL OR EXTERNAL PRESSURE

In this Subarticle equations are given for principal stresses and stress intensities resulting from uniformly distributed internal or external pressure in complete or partial spherical shells. The effects of discontinuities in geometry and loading are not included and should be evaluated independently. The stresses resulting from all effects must be combined by superposition.

A-3220 PRINCIPAL STRESSES AND STRESS INTENSITIES

A-3221 Principal Stresses Resulting From Internal Pressure

The principal stresses at any point in the wall of a spherical shell as a result of internal pressure are given by the following equations:

$$(1) \sigma_l = \sigma_t = p(Z^3 + 2)/2(Y^3 - 1)$$

$$(2) \sigma_2 = \sigma_t = p(Z^3 + 2)/2(Y^3 - 1)$$

$$(3) \sigma_3 = \sigma_r = p(1 - Z^3)/(Y^3 - 1)$$

A-3222 Stress Intensities Resulting From Internal Pressure

A-3222.1 General Primary Membrane Stress Intensity.

The general primary stress intensity in a spherical shell as a result of internal pressure is given by the following equation:

$$(4) S = 0.75p(Y^3 + 1)/(Y^3 - 1)$$

A-3222.2 Maximum Value of Primary Plus Secondary Stress Intensity.

The maximum value of the primary plus secondary stress intensity in a spherical shell

Page 206

as a result of internal pressure occurs at the inside surface and is given by the equation:

$$(5) S = 1.5p(Y^3)/(Y^3 - 1)$$

A-3223 Principal Stresses Resulting From External Pressure

The principal stresses at any point in the wall of a spherical shell resulting from external pressure are given by the following equations:

$$(6) \sigma_l = \sigma_t = -pY^3(U^3 + 2)/2(Y^3 - 1)$$

$$(7) \sigma_2 = \sigma_t = -pY^3(U^3 + 2)/2(Y^3 - 1)$$

$$(8) \sigma_3 = \sigma_r = pY^3(U^3 - 1)/(Y^3 - 1)$$

A-3224

A-3224.1 General Primary Membrane Stress Intensity.

The general primary membrane stress intensity in a spherical shell as a result of external pressure is given by the equation:

$$(9) S = 0.75p(Y^3 + 1)/(Y^3 - 1)$$

A-3224.2 Maximum Value of Primary Plus Secondary Stress Intensity.

The maximum value of the primary plus secondary stress intensity in a spherical shell as a result of external pressure occurs at the inside surface and is given by the equation:

$$(10) S = 1.5p(Y^3)/(Y^3 - 1)$$

NOTE: The equations in A-3223 and A-3224 may be used only if the applied external pressure is less than the critical pressure which would cause instability of the spherical shell. The value of the critical pressure must be evaluated in accordance with the rules given in NB-3133.4.

A-3230 BENDING ANALYSIS FOR UNIFORMLY DISTRIBUTED EDGE LOADS

A-3231 Scope and Limitations of Equations Given

(a) The equations in A-3230 describe the behavior of partial spherical shells of the types shown in Fig. A-3120-1 when subjected to the action of meridional bending moments M_o , in.-lb/in. of circumference, and forces H_o , lb/in. of circumference, uniformly distributed at the reference edge and acting at the mean radius of the shell. The effects of all other loading must be evaluated independently and combined by superposition.

(b) The equations listed in this paragraph become less accurate and should be used with caution when R_m/t is less than 10 or the opening angle limitations shown in Fig. A-3120-1 are exceeded.

A-3232 Displacement, Rotation, Moment, and Membrane Force in Terms of Loading Conditions at Reference Edge

The displacement δ , the rotation θ , the bending moments M_p, M_r , and the membrane forces N_p, N_t at any location of sphere are given in terms of the edge loads M_o and H_o by the following equations:

$$\begin{aligned}
\delta = M_o & \left\{ \frac{2\lambda^2}{Etk_1} F(\alpha)e^{-\lambda\alpha} [\cos(\lambda\alpha) - K_2 \sin(\lambda\alpha)] \right\} \\
& + H_o \left\{ \frac{R_m \lambda}{Etk_1} A_o \sin\phi_o F(\alpha)e^{-\lambda\alpha} [\cos(\lambda\alpha + \gamma_o) \right. \\
& \left. - K_2 \sin(\lambda\alpha + \gamma_o)] \right\} \quad (11)
\end{aligned}$$

$$\begin{aligned}
\theta = M_o & \left\{ \frac{4\lambda^3}{R_m Etk_1} C(\alpha)e^{-\lambda\alpha} \cos(\lambda\alpha) \right\} \\
& + H_o \left\{ \frac{2\lambda^2}{Etk_1} A_o \sin\phi_o C(\alpha)e^{-\lambda\alpha} \cos(\lambda\alpha + \gamma_o) \right\} \quad (12)
\end{aligned}$$

$$\begin{aligned}
M_l = M_o & \left\{ \frac{1}{k_1} C(\alpha)e^{-\lambda\alpha} [K_1 \cos(\lambda\alpha) + \sin(\lambda\alpha)] \right\} \\
& + H_o \left\{ \frac{R_m}{2\lambda k_1} A_o \sin\phi_o C(\alpha)e^{-\lambda\alpha} [K_1 \cos(\lambda\alpha \right. \\
& \left. + \gamma_o) + \sin(\lambda\alpha + \gamma_o)] \right\} \quad (13)
\end{aligned}$$

$$\begin{aligned}
M_t = M_o & \left\{ \frac{C(\alpha)}{2vk_1} e^{-\lambda\alpha} [B(\alpha) \cos(\lambda\alpha) + 2v^2 \sin(\lambda\alpha)] \right\} \\
& + H_o \left\{ \frac{R_m}{4v\lambda k_1} A_o \sin\phi_o C(\alpha) e^{-\lambda\alpha} [B(\alpha) \cos(\lambda\alpha \right. \\
& \left. + \gamma_o) + 2v^2 \sin(\lambda\alpha + \gamma_o)] \right\}
\end{aligned} \tag{14}$$

$$\begin{aligned}
N_t = -M_o & \left\{ \frac{2\lambda}{R_mk_1} C(\alpha) e^{-\lambda\alpha} \sin(\lambda\alpha) \cot(\phi_o - \alpha) \right\} \\
& - H_o \left[\frac{1}{K_1} A_o \cot(\phi_o - \alpha) (\sin \phi_o) C(\alpha) e^{-\lambda\alpha} \right. \\
& \left. \sin(\lambda\alpha + \gamma_o) \right]
\end{aligned} \tag{15}$$

$$\begin{aligned}
N_t = M_o & \left\{ \frac{2\lambda^2}{R_mk_1} C(\alpha) e^{-\lambda\alpha} \left[\cos(\lambda\alpha) \right. \right. \\
& \left. \left. - \left(\frac{K_1 + K_2}{2} \right) \sin(\lambda\alpha) \right] \right\} \\
& + H_o \left\{ \frac{\lambda}{k_1} A_o \sin\phi_o C(\alpha) e^{-\lambda\alpha} \left[\cos(\lambda\alpha + \gamma_o) \right. \right. \\
& \left. \left. - \left(\frac{K_1 + K_2}{2} \right) \sin(\lambda\alpha + \gamma_o) \right] \right\}
\end{aligned} \tag{16}$$

(14 - 16)

A-3233 Displacement and Rotation of Reference Edge in Terms of Loading Conditions at Reference Edge

A-3233.1 At Reference Edge Where $\alpha = 0$ and $\phi = \phi = \phi_o$

The equations for the displacement and rotation (A-3232) simplify to Eqs. (17) and (18) below:

$$\delta_o = M_o \frac{2\lambda^2 \sin \phi_o}{Etk_1} + H_o \frac{R_m \lambda \sin^2 \phi_o}{Et} \left(\frac{1}{k_1} + k_2 \right) \quad (17)$$

$$\theta_o = M_o \frac{4\lambda^3}{R_m Etk_1} + H_o \frac{2\lambda^2 \sin \phi_o}{Etk_1} \quad (18)$$

(17 - 18)

A-3233.2 When Shell Is a Full Hemisphere.

In the case where the shell under consideration is a full hemisphere Eqs. (17) and (18) above reduce to the following:

$$\delta_o = M_o \frac{2\lambda^2}{Et} + H_o \frac{2R_m \lambda}{Et} \quad (19)$$

$$\theta_o = M_o \frac{4\lambda^3}{R_m Et} + H_o \frac{2\lambda^2}{Et} \quad (20)$$

(19 - 20)

A-3234 Principal Stresses in Spherical Shells Resulting From Edge Loads

The principal stresses at the inside and outside surfaces of a spherical shell at any location, resulting from edge loads M_o and H_o are given by Eqs. (21), (22), and (23) below.

$$\sigma_1 = \sigma_l(\alpha) = \frac{N_l}{t} \pm \frac{6M_l}{t^2} \quad (21)$$

$$\sigma_2 = \sigma_t(\alpha) = \frac{N_t}{t} \pm \frac{6M_t}{t^2} \quad (22)$$

$$\sigma_3 = \sigma_r(\alpha) = 0 \quad (23)$$

(21 - 23)

In these equations, where terms are preceded by a double sign $\pm$, the upper sign refers to the inside surface of the shell and the lower sign refers to the outside surface.

A-3240 ALTERNATE BENDING ANALYSIS OF A HEMISPHERICAL SHELL SUBJECTED TO UNIFORMLY DISTRIBUTED EDGE LOADS

A-3241 Nature of Equations Given

If a less exacting but more expedient analysis of hemispherical shells is required, equations derived for cylindrical shells may be used in a modified form. The equations in A-3242 describe the behavior of a hemispherical shell as approximated by a cylindrical shell of the same radius and thickness when subjected to the action of uniformly distributed edge loads M_o and H_o at $\alpha = 0$, $x = 0$, and $\phi_o = 90$ deg.

Page 208

A-3242 Displacement, Rotation, Moment, and Shear Forces in Terms of Loading Conditions at

Edge

$$\delta_o = H_o / 2\beta^3 D + M_o / 2\beta^2 D \quad (24)$$

$$\theta_o = H_o / 2\beta^2 D + M_o / \beta D \quad (25)$$

$$\delta(x) = \frac{H_o \sin^2 \phi}{2\beta^3 D} f_1(\beta x) + \frac{M_o \sin \phi}{2\beta^2 D} f^2(\beta x) \quad (26)$$

$$\theta(x) = \frac{H_o \sin \phi}{2\beta^2 D} f_3(\beta x) + \frac{M_o}{\beta D} f_1(\beta x) \quad (27)$$

$$M(x) = \frac{H_o \sin \phi}{\beta} f_4(\beta x) + M_o f_3(\beta x) \quad (28)$$

(24 - 28)

$$Q(x) = H_o \sin \phi f_2(\beta x) - 2\beta M_o f_4(\beta x) \quad (29)$$

(29)

where f_1, f_2, f_3 , and f_4 are defined in A-2000, and

$$x = \alpha R_m = \frac{\pi R_m}{180 \text{ deg.}} (90 \text{ deg.} - \phi)$$

A-3243 Principal Stresses in Hemispherical Shell Due to Edge Loads

The principal stresses in a hemispherical shell due to edge loads M_o and H_o , at the inside and outside surfaces of a hemispherical shell at any meridional locations, are given by Eqs. (30), (31), and (32) below:

$$(30) \sigma_1 = \sigma_t(x) = \pm 6M(x)/t^2$$

$$(31) \sigma_2 = \sigma_l(x) = E\delta(x)/R_m \pm \nu 6M(x)/t^2$$

$$(32) \sigma_3 = \sigma_r = 0$$

In these equations, where terms are preceded by a double sign $\pm$, the upper sign refers to the inside surface of the hemisphere and the lower sign refers to the outside surface.

Page 209

ARTICLE A-4000 DESIGN CRITERIA AND EQUATIONS FOR TORISPHERICAL AND ELLIPSOIDAL HEADS

A-4100 INTRODUCTION

A-4110 SCOPE

The equations defining the curves in Fig. NC-3224.6-1 are summarized in this Article. The analysis is for pressure on the concave portion of the head and does not include effects of thermal gradients and loadings other than pressure.

A-4120 NOMENCLATURE

The nomenclature adopted in this Article is defined as follows:

t	= minimum required thickness of head, in.
r	= inside knuckle radius of torispherical head, in.
L	= inside crown radius of torispherical head, in.
D	= inside diameter of a head skirt, or inside length of the major axis of an ellipsoidal head, in.
P	= internal design pressure, psi
S	= membrane stress intensity limit from Section II, Part D, Subpart 1, Tables 2A and 2B multiplied by the stress intensity factors in Table NC-3217-1, psi

A-4130 METHOD USED TO DETERMINE DESIGN PRESSURE

The maximum internal pressure capacity or required thickness of a torispherical and ellipsoidal pressure vessel head is determined from the controlling criterion of primary membrane stress, elastic-plastic collapse load, buckling collapse, and fatigue. For thick heads, where $P/S > 0.08$ (approximately $t/L = 0.04$ to 0.05), primary membrane stress dominates. For thin heads, where $t/L > 0.002$, buckling collapse is the limiting condition. For the intermediate thickness heads, where $t/L > 0.002$ up to t/L , where $P/S < 0.08$ (approximately $t/L = 0.04$ to 0.05), elastic-plastic collapse pressure and fatigue due to pressurization cycles are the determining conditions. At the present time, only design of the intermediate thickness heads is considered in this Division.

A-4140 MATHEMATICAL EXPRESSIONS FOR CURVES IN FIG. NC-3224.6-1

The equation for computing A for given set of parameters r/D and P/S is as follows:

$$(1) A = a_1 + a_2x + a_3x^2 + (b_1 + b_2x + b_3x^2)y + (c_1 + c_2x + c_3x^2)y^2$$

where

$$(2) x = r/D$$

$$(3) y = \text{logarithm } P/S$$

Constants a_1 through c_3 are given in A-4141 for natural logarithms and in A-4142 for common base logarithms.

A-4141 Natural Logarithms

$$(4) y = \ln (P/S)$$

$$(5) t/L = e^A$$

and

$$a_1 = -1.2617702$$

$$b_1 = 0.66298796$$

$$c_1 = 0.26878909 \times 10^{-4}$$

$$a_2 = -4.5524592$$

$$b_2 = -2.2470836$$

$$c_2 = -0.42262179$$

$$a_3 = 28.933179$$

$$b_3 = 15.682985$$

$$c_3 = 1.8878333$$

A-4142 Common Base Logarithms

$$(6) y = \log_{10}(P/S)$$

$$(7) t/L = 10^A$$

and

$$a_1 = -0.5479782$$

$$b_1 = 0.66298796$$

$$c_1 = 0.61890975 \times 10^{-4}$$

$$a_2 = -1.9771079$$

$$b_2 = -2.2470836$$

$$c_2 = -0.97312263$$

$$a_3 = 12.565520$$

$$b_3 = 15.682985$$

$$c_3 = 4.3468967$$

A-4150 SAMPLE PROBLEM

Consider a torispherical head having the parameters $L = 84$ in.; $D = 90$ in.; $r = 5.5$ in.; $P = 200$ psi; and for material SA-515 Grade 70, $S = 23,300$ psi. With these data and using Eq. (1) in A-4140 and the common logarithms and constants of A-4142:

$$P/S = 0.00858369$$

$$P/S = 0.06111111 = x$$

$$y = \log (P/S) = -2.066325925$$

and

$$y^2 = 4.269702828$$

$$A = -2.013430932$$

Solving Eq. (1) of A-4140:

$$t/L = 10^A = 0.009695474$$

$$t = 0.814 \text{ in.}$$

Direct reading of Fig. NC-3224.6-1 gives the following:

$$t/L = 0.0097$$

$$t = 0.814 \text{ in.}$$

ARTICLE A-5000 ANALYSIS OF FLAT CIRCULAR HEADS

A-5100 INTRODUCTION

A-5110 SCOPE

(a) In this Article equations are given for stresses and displacements in flat circular plates used as heads for pressure vessels.

(b) Equations are also given for stresses and displacements in these heads due to forces and edge moments uniformly distributed along the outer edge, and uniformly distributed over a circle on one face. The radius of this circle is intended to match the mean radius of an adjoining element, such as a cylinder, cone, or spherical segment.

A-5120 NOMENCLATURE AND SIGN CONVENTION

The symbols and sign conventions adopted in this Article are defined as follows:

p	= pressure, psi
M	= radial bending moment, in.-lb/in. of circumference
Q	= radial force, lb/in. of circumference
σ_r	= radial stress, psi
σ_l	= longitudinal stress, psi
σ_t	= tangential (circumferential) stress, psi
w	= radial displacement, in.
θ	= rotation, rad
R	= outside radius of plate, in.
r	= radial distance from center of plate, in.
x	= longitudinal distance from midplane of plate, in.
t	= thickness of plate, in.
t_s	= thickness of connecting shell at the head junction, in.
E	= elastic modulus, psi
ν	= Poisson's ratio
F	= geometry constant, given in Table A-5240-1
$\ln$	= $\log_e$

Tensile stresses are positive. The positive directions of the coordinates, radial forces, moments, and displacements are shown in Fig. A-5120-1. The pressure is assumed to act on the surface where $x = t/2$.

FIG. A-5120-1

A-5200 LOADS, DISPLACEMENTS, AND GEOMETRY CONSTANTS

A-5210 PRESSURE AND EDGE LOADS ON CIRCULAR FLAT PLATES

A-5211 Values for Which Equations Are Given

In this Subarticle equations are given for the principal stress and the deformations of flat plates under axisymmetric loading conditions.

A-5212 Pressure Loads on Simply Supported Flat Plates

The principal stresses and deformations for a flat plate, simply supported at its periphery and loaded in the manner shown on Fig. A-5120-1 are given for a radial location r at any point x in the cross section by Eqs. (1) through (6) below.

FIG. A-5212-1

FIG. A-5212-1

Radial bending stress:

$$\sigma_r = p \frac{3(x)}{4t^3} [(3 + \nu) (R^2 - r^2)] \quad (1)$$

(1)

Tangential bending stress:

$$\sigma_r = p \frac{3(x)}{4t^3} [(3 + \nu) R^2 - (1 + 3\nu) r^2] \quad (2)$$

(2)

Longitudinal stress:

$$(3) \sigma_l = (p/t)(x - t/2)$$

Rotation of the midplane:

$$\theta = -p \frac{3(1 - \nu)}{4t^3 E} [r^3 (1 + \nu) - rR^2 (3 + \nu)] \quad (4)$$

(4)

Rotation of the midplane at the outer edge:

$$(5) \theta = +p [3(1 - \nu)/2E](R/t)^3$$

Radial displacement:

$$(6) w = +(x)\theta$$

A-5213 Edge Loads on Flat Plates

The principal stresses and deformations of a flat plate subjected to uniformly distributed edge loads, as shown on Fig. A-5213-1 are given for radial location r at any point x in the cross section by the following equations:

FIG. A-5213-1

FIG. A-5213-1

Radial and tangential stresses:

$$\sigma_r = \sigma_t = \frac{Q}{t} - \frac{12(x)}{t^3} M \quad (7)$$

(7)

Rotation of the midplane:

$$\theta = \frac{-12(1 - \nu)(r)}{Et^3} M \quad (8)$$

(8)

Radial displacement:

$$w = \frac{(1 - \nu)(r)}{Et} Q + (x) \theta \quad (9)$$

(9)

A-5220 FLAT PLATE PRESSURE VESSEL HEADS

A-5221 Methods of Attachment

Flat plates used as pressure vessel heads are attached to a vessel shell in the manner shown by the typical examples in Fig. A-5221-1

formed by the head and the shell may be analyzed according to the principles of discontinuity analysis described in A-6000. In the following paragraph, equations are given for the quantities necessary to perform a discontinuity analysis.

FIG. A-5221-1

FIG. A-5221-1

A-5222 Displacements and Principal Stresses in a Flat Head

The head is assumed to be separated from the adjoining shell element and under the action of the pressure load. Figure A-5222-1 illustrates this condition. The effects of the adjacent shell are represented by the pressure reaction force, the discontinuity force Q , and the discontinuity moment M . These act at the assumed junction point a . The pressure acts on the left-hand face over a circular area defined by the inside radius of the adjacent shell. The support point lies on this same face at the midradius of the adjacent shell. The equations in this paragraph are given in terms of the head dimensions R and t and multiplying factors F_1 to F_4 . These factors reflect the extent of the pressure area and the location of the junction point. The numerical values for F_1 to F_4 are given in Table A-5240-1. These are functions of the ratio of the shell thickness t_s to the head radius R .

A-5223 Displacements of a Flat Head

A-5223.1 Displacements Due to Pressure.

For a plate simply supported at a point a , the rotational displacement θ_p and the radial displacement w_p of point a , due to pressure p acting over the area defined by the radius $(R - t_s)$, are given by Eqs. (10) and (11) below:
(10 - 11)

FIG. A-5222-1

FIG. A-5222-1

A-5223.2 Displacements Due to Radial Force and Moment.

The rotational displacements θ and the radial displacement w of point a , due to a uniformly distributed radial force Q and moment M acting at point a , are given by Eqs. (12) and (13) below:

$$\theta = \frac{-F_3}{ER(t/R)^2} Q + \frac{-2F_3}{ER^2(t/R)^3} M \quad (12)$$

$$w = \frac{2F_3}{3E(t/R)} Q + \frac{F_3}{ER(t/R)^2} M \quad (13)$$

(12 - 13)

A-5224 Principal Stresses in a Flat Head

When the values of the discontinuity force Q and the moment M have been determined by a discontinuity analysis, the principal stresses in a flat plate can be calculated in the following subparagraphs.

A-5224.1 Radial Stress Due to Pressure.

For a plate simply supported at point a , the radial stress σ_r for a radial location r less than $(R - t_s)$ at any point x , due to pressure p acting over the area defined by the radius $(R - t_s)$, is given by the following equation:

Page 214

$$\sigma_r = \frac{(x)p}{t(t/R)^2} \left[(F_2) - \frac{3(3 + \nu)r^2}{4R^2} \right] \quad (14)$$

(14)

A-5224.2 Tangential and Axial Stresses Due to Pressure.

For these same conditions, the tangential stress σ_t and the axial stress σ_z are given by Eqs. (15) and (16) below:

$$\sigma_t = \frac{(x)p}{t(t/R)^2} \left[(F_2) - \frac{3(1 + 3\nu)r^2}{4R^2} \right] \quad (15)$$

$$\sigma_t = (p/t)(x - t/2) \quad (16)$$

(15 - 16)

A-5224.3 Radial and Tangential Stresses Due to Radial Force and Moment.

The radial stress σ_r and the tangential stress σ_t for any radial location at any point x in the cross section, due to uniformly distributed radial force Q and a uniformly distributed moment M acting at point a , are given by the equation:

$$\sigma_r = \sigma_t = \frac{F_4}{t} \left[1 - \frac{6(x)}{t} \right] Q - \frac{12F_4(x)}{t^3} M \quad (17)$$

(17)

A-5240 GEOMETRY CONSTANTS

The geometry constants F_1 through F_4 are functions of Poisson's ratio and t_s/R . These are given in Eqs. (18) through (21) below:

$$F_1 = \frac{3(1 - \nu)(2 - f^2)(1 - f)^2 [8 - f(4 - f)(1 - \nu)]}{16(2 - f)} \quad (18)$$

$$F_2 = \frac{3}{8}(1 - f)^2 \left\{ (1 - \nu)(2 - f^2) + 4(1 + \nu) \right. \\ \left. \times \left[1 + 2 \ln \frac{2 - f}{2 - 2f} \right] \right\} \quad (19)$$

(18 - 19)

$$F_3 = \frac{3}{8}(1 - \nu)(2 - f)[8 - f(4 - f)(1 - \nu)] \quad (20)$$

$$F_4 = \frac{1}{8}[8 - f(4 - f)(1 - \nu)] \quad (21)$$

(20 - 21)

TABLE A-5240-1

TABLE A-5240-1

In these equations

$$f = t_s/R$$

Table A-5240-1 lists these functions for various values of t_s/R . These tabular values have been computed using 0.3 for Poisson's ratio.

A-5250 STRESS INTENSITIES IN A FLAT PLATE

The principal stresses due to pressure p , discontinuity force Q , discontinuity moment M , and other coincident loadings should be combined algebraically and the stress differences determined according to the procedures of NB-3215. The calculated stress intensity values should not exceed the stress limits given in NB-3220.

Page 215

ARTICLE A-6000 DISCONTINUITY STRESSES

A-6100 INTRODUCTION

A-6110 SCOPE

(a) Pressure vessels usually contain regions where abrupt changes in geometry, material, or loading occur. These regions are known as *discontinuity areas* and the stresses associated with them are known as *discontinuity stresses*. The discontinuity

stresses are required to satisfy the compatibility of deformations of these regions.

(b) This Article describes a general procedure for analyzing the discontinuity stresses. A numerical example is included to illustrate the procedure.

(c) To determine the principal stresses at a discontinuity, it is necessary to evaluate the stresses caused by (1) pressure; (2) mechanical loads; (3) thermal loads; and (4) discontinuity loads. The stress intensities are then obtained by superposition of the stresses according to the rules given in NB-3220.

A-6120 INFORMATION REQUIRED

In order to perform a discontinuity analysis, the following information must be known:

- (a) the dimensions of the vessel;
- (b) the material properties (E , α , ν) of the component parts of the vessel (A-7120);
- (c) mechanical loads, such as pressure, dead weight, bolt loads, and pipe loads;
- (d) temperature distribution in the component parts.

A-6200 METHOD OF AND PROCEDURE FOR DISCONTINUITY ANALYSIS

A-6210 METHOD

(a) The analysis of a pressure vessel containing discontinuity areas can be performed in a standard manner similar to the analysis of any statically indeterminate structure. The analysis is initiated by separating the vessel into shell elements of simple geometry, such as rings and cylinders, of which the structural behavior is known. The pressure, mechanical, and thermal loads acting on the structure are applied to the shell elements with a system of forces required to maintain the static equilibrium of each element. These loads and forces cause individual elements deformations, which in general are not equal at the adjoining edges. The deformations at an element edge are defined as:

- (1) radial displacement
- (2) rotation of the meridian tangent

A redundant moment and shear force must generally exist on the edges of the elements, in order to have compatibility of deformations, and restore continuity in the structure.

(b) At each juncture discontinuity, two equations can be written which express the equality of the combined deformations due to all the applied loads and the redundant forces and moments. One equation will express the equality of rotation, the other equation the equality of displacement of the adjacent elements. The resulting system of simultaneous equations can be solved to obtain the redundant moment and shear force at each juncture.

A-6220 PROCEDURE

A-6221 Basic Steps

The basic steps to follow for determining the redundant shear and moment that may exist at a pressure vessel discontinuity are given in (a) through (f) below.

- (a) Separate the vessel into individual shell elements at locations of discontinuity.
- (b) Calculate the edge deformations of each element, caused by a unit shear force and a unit moment at each edge. These values are known as influence coefficients. The deformations due to local flexibilities may be considered in the calculation of these influence coefficients.

FIG. A-6230-1

FIG. A-6230-1

- (c) Calculate the edge deformations of each element, caused by loads other than redundant loads.
- (d) Calculate the edge deformations of each element, caused by the temperature distributions.
- (e) At each juncture of two elements equate the total radial displacements and the total rotations of each element.
- (f) Solve the final system of simultaneous equations for the redundant shears and moments.

[98]

A-6222 Stresses

When the values of the redundant shear forces and moments have been determined, the stresses resulting from the redundant loadings may be computed by conventional methods. The final stresses for each element are determined by combining these stresses with the stresses which would exist in the individual shell elements of A-6230, Step 1.

[98]

[98]

A-6230 EXAMPLE ILLUSTRATING APPLICATION OF A-6221

Given

A pressure vessel as shown in Fig. A-6230-1. It is constructed of SA-533, Grade B, Class 1 steel and subjected to an internal pressure of 950 psi at 300°F. The vessel consists of the following:

(a) a hemispherical head with:

inside radius $R = 30$ in.

thickness $t = 1.375$ in.

(b) a cylindrical shell with:

inside radius $R = 30$ in.

thickness $t = 1.375$ in.

length $L = 10$ in.

(c) a flat head with:

outside radius $R = 31.375$ in.

thickness $t = 6$ in.

The material properties assumed are:

$$E = 29 \times 10^6 \text{ psi}$$

$$\nu = 0.3$$

Required

To calculate the discontinuity stresses at the locations of structural discontinuity.

Solution

Step 1. Separate the vessel at locations of discontinuity into individual elements.

Step 2. Calculate the influence coefficients.

(a) *Element A, Hemispherical Head.* From A-3233.2, the lateral displacement and rotation at juncture O due to edge loads Q_o and M_o are given as:

$$w_{AO} = \delta_{AO} = -\frac{2R_m\lambda}{Et} Q_o + \frac{2\lambda^2}{Et} M_o$$

$$\theta_{AO} = -\frac{2\lambda^2}{Et} Q_o + \frac{4\lambda^3}{R_m Et} M_o$$

NOTE: For this case of a hemispherical shell the lateral force H and the radial force Q are equal. Similarly the lateral displacement δ and the radial displacement w are equal.

Substituting the given dimensions and material properties gives:

$$w_{AO} = \delta_{AO} = (-9.346755Q_o + 1.849564M_o) \times 10^{-6}$$

$$\theta_{AO} = (-1.849564Q_o + 0.731995M_o) \times 10^{-6}$$

(b) *Element B, Cylindrical Shell (See Fig. A-6230-2).* From A-2243, the radial displacements and rotations at the edges O and L due to edge loadings Q_o, M_o, Q_L , and M_L are given as follows:

$$w_{BO} = (B_{11}/2\beta^3 D)Q_o + (B_{12}/2\beta^2 D)M_o \\ + (G_{11}/2\beta^3 D)Q_L + (G_{12}/2\beta^2 D)M_L$$

$$-\theta_{BO} = (B_{12}/2\beta^2 D)Q_o + (B_{22}/\beta D)M_o \\ + (G_{12}/2\beta^2 D)Q_L + (G_{22}/2\beta D)M_L$$

$$w_{BL} = (G_{11}/2\beta^3 D)Q_o + (G_{12}/2\beta^2 D)M_o \\ + (B_{11}/2\beta^3 D)Q_L + (B_{12}/2\beta^2 D)M_L$$

$$\theta_{BL} = (G_{12}/2\beta^2 D)Q_o + (G_{22}/2\beta D)M_o \\ + (B_{12}/2\beta^2 D)Q_L + (B_{22}/\beta D)M_L$$

FIG. A-6230-2

FIG. A-6230-2

Substituting given dimensions and material properties gives:

$$w_{BO} = (10.697309Q_o + 2.114906M_o \\ - 3.812809Q_L - 1.025641M_L) \times 10^{-6}$$

$$-\theta_{BO} = (2.114906Q_o + 0.792367M_o \\ - 1.025641Q_L - 0.123127M_L) \times 10^{-6}$$

$$w_{BL} = (- 3.812809Q_o - 1.025641M_o \\ + 10.697309Q_L + 2.114906M_L) \times 10^{-6}$$

$$\theta_{BL} = (- 1.025641Q_o - 0.123127M_o$$

$$+ 2.114906 Q_L + 0.792367 M_L) \times 10^{-6}$$

FIG. A-6230-3

FIG. A-6230-3

(c) *Element C, Flat Head.* From A-5223.2, the radial displacement and rotation at juncture L due to edge loadings Q_L and M_L are given as follows:

$$w_{CL} = -\frac{2F_3}{3E(t/R)} Q_L + \frac{F_3}{ER(t/R)^2} M_L$$

$$\theta_{CL} = \frac{F_3}{ER(t/R)^2} Q_L - \frac{2F_3}{ER^2(t/R)^3} M_L$$

Substituting given dimensions and material properties gives:

$$w_{CL} = [-0.486330Q_L + 0.121583M_L] \times 10^{-6}$$

$$\theta_{CL} = [0.121583Q_L - 0.040530M_L] \times 10^{-6}$$

Step 3. Calculate the edge deformations due to the internal pressure.

(a) *Element A, Hemispherical Shell (See Fig. A-6230-3).* The lateral displacement of point O at the midsurface ($r=R_m$) of a hemispherical shell subjected to internal pressure is given by the expression:

$$w_o = \delta_o = p \frac{R^3}{2E(R_o^3 - R^3)R_m^2} [2R_m^3(1 - 2\nu) + R_o^3(1 + \nu)]$$

FIG. A-6230-4

FIG. A-6230-4

Substituting the dimensions, pressure, and material properties gives:

$$W_{AO(\text{pressure})} = 7647 \times 10^{-6}$$

NOTE: An alternative expression may be used for the displacement of a thin hemispherical shell:

$$w = (1 - \nu)(pR^2/2Et)$$

There is no rotation resulting from the internal pressure and membrane forces as shown:

$$\theta_{AO(\text{pressure})} = 0$$

(b) *Element B, Cylindrical Shell (See Fig. A-6230-4).* The radial displacement of the midsurface of a closed end cylindrical shell subjected to internal pressure is given by the expression:

$$w = p \frac{R^2}{E(R_o^2 - R^2)R_m} [R_m^2(1 - 2\nu) + R_o^2(1 + \nu)]$$

Substituting the dimensions, pressure, and material properties gives:

—

$$w_{BO(\text{pressure})} = w_{BL(\text{pressure})} = 18,857 \times 10^{-6}$$

NOTE: An alternative expression may be used for displacement of a thin cylindrical shell:

$$w = [1 - (\nu/2)] (pRR_m/Et)$$

FIG. A-6230-5

FIG. A-6230-5

There is no rotation resulting from internal pressure and the membrane forces as shown:

$$\theta_{BO(\text{pressure})} = \theta_{BL(\text{pressure})} = 0$$

(c) *Element C, Flat Head* (See Fig. A-6230-5). The rotation of a flat head at point L due to internal pressure is given by Eq. (10) in A-5223.1:

$$\theta = \frac{F_1}{E(t/R)^3} p$$

Substituting the dimensions, pressure, and material properties gives:

$$\theta_{CL(\text{pressure})} = 4523 \times 10^{-6}$$

The radial displacement at juncture L is given by Eq. (11) in A-5223.1:

$$w_{CL(\text{pressure})} = -\frac{t}{2} \theta_{CL} = -13,570 \times 10^{-6}$$

Step 4. Calculate the free deformations of the edges of each element caused by temperature distributions.

In this example all parts of the vessel are at the same temperature and are of the same material; therefore, temperature deformations need not be considered.

Page 219

Step 5. Equate the total lateral displacements and rotations of adjacent elements at each juncture.

(a) *Juncture O*

$$w_{AO(\text{total})} = w_{BO(\text{total})}$$

$$(-9.346755Q_o + 1.849564M_o + 7647) \times 10^{-6}$$

$$= (10.697309Q_o + 2.114906M_o - 3.812809Q_L$$

$$- 1.025641M_L + 18,857) \times 10^{-6} \quad (1)$$

$$\theta_{AO(\text{total})} = \theta_{BO(\text{total})}$$

$$(-1.849564Q_o + 0.731995M_o + 0) \times 10^{-6}$$

$$= (-2.114906Q_o - 0.792367M_o + 1.025641Q_L$$

$$+ 0.123127M_L + 0) \times 10^{-6} \quad (2)$$

(1 - 2)

(b) *Juncture L*

$$w_{BL(\text{total})} = w_{CL(\text{total})}$$

$$(-3.812809Q_o - 1.025641M_o + 10.697309Q_L$$

$$+ 2.114906M_L + 18,857) \times 10^{-6}$$

$$= (-0.486330Q_L + 0.121583M_L - 13,570) \times 10^{-6} \quad (3)$$

$$\theta_{BL(\text{total})} = \theta_{CL(\text{total})}$$

$$(-1.025641Q_o - 0.123127M_o + 2.114906Q_L$$

$$+ 0.792367M_L + 0) \times 10^{-6} = (0.121583Q_L$$

$$-0.040530M_L + 4523) \times 10^{-6} \quad (4)$$

(3 - 4)

Combining like terms and multiplying through by 10^6 results in the following system of simultaneous equations which express compatibility at the junctures:

$$(5) -20.04364Q_o - 0.265342M_o + 3.812809Q_L + 1.025641M_L = 11,210$$

$$(6) 0.265342Q_o + 1.524362M_o - 1.025641Q_L - 0.123127M_L = 0$$

$$(7) -3.812809Q_o - 1.025641M_o + 11.183639Q_L + 1.993323M_L = -32,427$$

(8)

$o \qquad o \qquad L \qquad L$

Step 6. Solve the above equation for Q_o , M_o , Q_L , and M_L . The results are:

$$Q_o = 807 \text{ lb/in.} = -0.807 \text{ kips/in.}$$

$$M_o = -3018 \text{ in.-lb/in.} = -3.018 \text{ in.-kips/in.}$$

$$Q_L = 7259 \text{ lb/in.} = -7.259 \text{ kips/in.}$$

$$M_L = 21,363 \text{ in.-lb/in.} = 21.363 \text{ in.-kips/in.}$$

NOTE: A negative sign indicates that the actual direction of the loading is opposite to that chosen in Step 1.

Step 7. Compute the discontinuity stresses at each juncture due to the redundants Q_o , M_o , Q_L , and M_L . To illustrate the procedure, these stresses will be computed in the cylindrical shell element B at both junctures O and L . From A-2260:

$$\sigma_t(x) = \pm 6M(x)/t^2$$

$$\sigma_t(x) = Ew(x)/(R + t/2) \pm 6vM(x)/t^2$$

$$\sigma_r = 0$$

(a) *Juncture O.* At juncture O , $M(x) = M_o$ and $w(x) = w_o$.

NOTE: When computing $\sigma_t(x)$ only the radial displacement due to the redundant shear forces and moments should be used. The free displacements from Steps 3 and 4 should not be included.

Page 220

$$w_{BO} = (10.697309Q_o + 2.114906M_o - 3.812809Q_L - 1.025641M_L) \times 10^{-6} = -0.009007 \text{ in.}$$

$$Ew_{BO} = -261.20 \text{ kips/in.}$$

$$M_o = -3.018 \text{ in.-kips/in.}$$

(1) Inside surface:

$$\sigma_t = 6(-3.018)/(1.375)^2 = -9.6 \text{ ksi}$$

$$\sigma_t = (-261.20/30.6875) + 6(0.3)(-3.02)/(1.375)^2 = -11.5 \text{ ksi}$$

$$\sigma_r = 0$$

(2) Outside surface:

$$\sigma_t = -6(-3.018)/(1.375)^2 = 9.6 \text{ ksi}$$

$$\sigma_t = (-261.20/30.6875) - 6(0.3)(-3.018)/(1.375)^2 = -5.6 \text{ ksi}$$

$$\sigma_r = 0$$

(b) *Juncture L.* At juncture L , $M(x) = M_L$ and $w(x) = w_L$.

$$w_{BL} = (-3.812809Q_o - 1.025641M_o + 10.697309Q_L + 2.114906M_L) \times 10^{-6} = -0.026299 \text{ in.}$$

$$Ew = -762.67 \text{ kips/in.}$$

BL

$$M_L = 21.363 \text{ in.-kips/in.}$$

(1) Inside surface:

$$\sigma_l = 6(21.363)/(1.375)^2 = 67.8 \text{ ksi}$$

$$\sigma_t = (-762.67/30.6875) + 6(0.3)(21.363)/(1.375)^2 = -4.5 \text{ ksi}$$

$$\sigma_r = 0$$

(2) Outside surface:

$$\sigma_l = -6(21.363)/(1.375)^2 = -67.8 \text{ ksi}$$

$$\sigma_t = (-762.67/30.6875) - 6(0.3)(21.363)/(1.375)^2 = -45.2 \text{ ksi}$$

$$\sigma_r = 0$$

NOTE: $E = 29 \times 10^6$ psi.

(c) The discontinuity stresses in the hemispherical shell may be computed by using the expressions given in A-3232 and A-3234.

(d) The discontinuity stresses in the flat head may be computed using the expressions given in A-5224.

Step 8. Compute the total stresses. The total stresses may be computed in any element at any juncture by combining the stresses due to the redundant shear forces and moments as computed in Step 7, with the stresses resulting from all other loadings. In this case the stresses in the cylindrical shell, hemispherical shell, and flat head due to internal pressure may be computed by the expressions given in A-2212, A-3221, and A-5224, respectively. To illustrate the procedure the total stresses in the cylindrical shell at junctures *O* and *L* will be computed. The stresses in the cylindrical shell due to internal pressure may be computed from Eqs. (1), (2), and (3) in A-2212:

$$\sigma_l = p/(Y^2 - 1)$$

$$\sigma_t = p(1 + Z^2)/(Y^2 - 1)$$

$$\sigma_r = p(1 - Z^2)/(Y^2 - 1)$$

(a) *Juncture O*

(1) Inside surface:

Page 221

$$Y = Z = R_o/R = 31.375/30.000 = 1.04583$$

$$p = 950 \text{ psi}$$

$$\sigma_l = 10,132 \text{ psi B } 10.1 \text{ ksi}$$

$$\sigma_t = 21,214 \text{ psi B } 21.2 \text{ ksi}$$

$$\sigma_r = -950 \text{ psi B } -1 \text{ ksi}$$

The stresses due to the redundant shear forces and moments were computed in Step 7 as:

$$\sigma_l = -9.6 \text{ ksi}$$

$$\sigma_t = -11.5 \text{ ksi}$$

$$\sigma_r = 0$$

The total stresses are:

$$\sigma_l = 10.1 + (-9.6) = 0.5 \text{ ksi}$$

$$\sigma_t = 21.2 + (-11.5) = 9.7 \text{ ksi}$$

$$\sigma_r = -0.95 + 0 = -1.0 \text{ ksi}$$

(2) Outside surface:

$$Z = 1$$

$$Y = 1.04583$$

$$\sigma_l = 10,132 \text{ psi} \approx 10.1 \text{ ksi}$$

$$\sigma_t = 20,264 \text{ psi} \approx 20.3 \text{ ksi}$$

$$\sigma_r = 0$$

The stresses due to the redundant shear forces and moments were computed as:

$$\sigma_l = 9.6 \text{ ksi}$$

$$\sigma_t = -5.6 \text{ ksi}$$

$$\sigma_r = 0$$

The total stresses are:

$$\sigma_l = 10.1 + (9.6) = 19.7 \text{ ksi}$$

$$\sigma_t = 20.3 + (-5.6) = 14.7 \text{ ksi}$$

$$\sigma_r = 0 + 0 = 0$$

(b) *Juncture L*

(1) *Inside Surface.* The stresses due to the internal pressure are the same as at juncture O:

$$\sigma_l = 10.1 \text{ ksi}$$

$$\sigma_t = 21.2 \text{ ksi}$$

$$\sigma_r = -1.0 \text{ ksi}$$

The stresses due to the redundant shear forces and moments were computed as:

$$\sigma_l = 67.8 \text{ ksi}$$

$$\sigma_t = -4.5 \text{ ksi}$$

$$\sigma_r = 0$$

The total stresses are:

$$\sigma_t = 10.1 + (67.8) = 77.9 \text{ ksi}$$

$$\sigma_t = 21.2 + (-4.5) = 16.7 \text{ ksi}$$

$$\sigma_r = -0.95 + 0 = -1.0 \text{ ksi}$$

(2) *Outside Surface.* The stresses due to the internal pressure are the same as at juncture *O*:

Page 222

$$\sigma_t = 10.1 \text{ ksi}$$

$$\sigma_t = 20.3 \text{ ksi}$$

$$\sigma_r = 0$$

The stresses due to redundant shear forces and moments were computed as:

$$\sigma_t = -67.8 \text{ ksi}$$

$$\sigma_t = -45.2 \text{ ksi}$$

$$\sigma_r = 0$$

The total stresses are:

$$\sigma_t = 10.1 + (-67.8) = -57.7 \text{ ksi}$$

$$\sigma_t = 20.3 + (-45.2) = -24.9 \text{ ksi}$$

$$\sigma_r = 0 + 0 = 0$$

Step 9

(a) When evaluating the stresses in accordance with NB-3222.2, the stress intensities at each location should be computed from the total principal stresses determined in Step 8.

(b) When evaluating the stresses in accordance with NB-3222.4(b), it is necessary to consider the influence of local stress concentrations upon the principal stresses determined in Step 8 before computing the stress intensities.

[98]

Page 223

ARTICLE A-7000 THERMAL STRESSES

A-7100 INTRODUCTION

A-7110 OCCURRENCE OF THERMAL STRESSES AND DISPLACEMENTS

(a) Thermal stresses occur in a system, or part of a system, when thermal displacements (expansions or contractions) which would otherwise freely occur are partially or completely restrained.

(b) Thermal displacements may be induced by temperature distributions caused by heat transfer and internal heat generation.

[98]

A-7120 INFORMATION NECESSARY TO CALCULATE THERMAL STRESSES

(a) In order to calculate thermal stresses, the information stipulated in (1), (2), and (3) below must usually be known for each member comprising the system:

(1) the dimensions;

(2) the temperature distribution T as a function of a suitable coordinate system;

(3) the material properties: modulus of elasticity E , Poisson's ratio ν , and coefficient of thermal expansion α , where E and α are temperature dependent quantities (Tables TE and TM of Section II, Part D, Subpart 2 provide these values).

(b) Frequently, it is accurate enough to consider E and α for each material as constant at their instantaneous values for the average temperature of the temperature range under consideration. If the lower limit of the temperature range is ambient, the instantaneous value of α for the average temperature coincides with the mean coefficient of thermal expansion.

(c) During transient conditions, the temperature distribution and thermal stresses vary with time. The analysis, therefore, requires consideration of the thermal stresses as a function of time during the transient.

[98]

A-7130 METHOD OF CALCULATION

If closed form expressions for the thermal stresses are not available, the procedure of (a) through (e) below may be used for computing the thermal stress for a specified time θ .

(a) Express the temperature distribution T for each component as a function of the space coordinates t , l , and r .

(b) Divide the system, which may be of irregular shape or of complex geometry, into free bodies of simple shape, such as rings, cylinders, and spherical shells.

(c) Calculate the free body stresses and deformations for each component resulting from the temperature distribution.

(d) Calculate the discontinuity thermal stresses by means of discontinuity analysis as described in A-6000.

(e) Superimpose the stresses determined in (c) and (d) above to obtain the combined thermal stresses.

Page 224

ARTICLE A-8000 STRESSES IN PERFORATED FLAT PLATES

A-8100 INTRODUCTION

A-8110 SCOPE

(a) This Article contains a method of analysis for flat perforated plates when subjected to directly applied loads or loadings resulting from structural interaction with adjacent members. This method applies to perforated plates which satisfy the conditions of (1) through (5) below.

(1) The holes are in an array of equilateral triangles.

(2) The holes are circular.

(3) There are 19 or more holes.

(4) The ligament efficiency is greater than 5% ($\eta \geq 0.05$).

(5) The plate is thicker than twice the hole pitch ($t/P \geq 2$). If only in-plane loads or thermal skin stresses are considered, this limitation does not apply.

(b) Credit may be taken for the stiffening effect of the tubes in the perforations. The extent to which the tubes stiffen the perforated plate depends on the materials, the manufacturing processes, operating conditions, and degree of corrosion. This stiffening effect may be included in the calculations by including part or all of the tube walls in the ligament efficiency used to obtain the effective elastic constants of the plate. Such stiffening may either increase or decrease stresses in the plate itself and in the attached shells.

(c) Credit may be taken for the staying action of the tubes where applicable.

A-8120 NOMENCLATURE

h	= nominal width of ligament at the minimum cross section, in.
P	= nominal distance between hole center lines, pitch, in.
t	= thickness of plate exclusive of cladding or corrosion allowance, in.
η	= ligament efficiency = h/P
ν^*	= effective Poisson's ratio for perforated plate (Fig. A-8131-1)
E^*	= effective Young's modulus for perforated plate (Fig. A-8131-1), psi
R^*	= the effective radius of the perforated plate, in. = $r_o + 1/4 (P - h)$
r_o	= radial distance from center of plate to center of outermost hole, in.
p_1, p_2	= pressures acting on surfaces of the plate, psi
Δp	= differential pressure across the plate
σ_r	= radial stresses in the equivalent solid plate, psi
σ_θ	= tangential stress in the equivalent solid plate, psi
β	= biaxiality ratio σ_r/σ_θ or σ_θ/σ_r (σ_1/σ_2 or σ_2/σ_1), where $-1 \leq \beta \leq 1$
σ_{ave}	= larger absolute value of σ_r or σ_θ [A-8142.1(b)]
$\bar{\sigma}_r$	= radial stress averaged through the depth of the equivalent solid plate, psi
σ_1, σ_2	= principal stress in the plane of the equivalent solid plate (A-8142.2), psi
σ_{rim}	= nominal circumferential stress in solid rim, psi
σ_{skin}	= thermal skin stress, psi
r	= designation of radial location in plate
ρ	= radius of holes in the plate, in.
K	= stress multiplier for stresses averaged across the width of the ligament but not through the thickness (Fig. A-8142-1)
Y	= stress multiplier for peak ligament stresses (Fig. A-8142-1)

K_m	= ratio of peak stress in reduced ligament to the peak stress in normal ligament
K_{skin}	= stress multiplier for thermal skin stress (Fig. A-8153-1)
K_r	= stress multiplier for circumferential stress in the plate rim (Fig. A-8142-6)
S	= stress intensity (A-8142), psi
w	= radial displacement of plate edge, in.
θ	= rotation of plate edge, rad

Page 225

Q	= radial force acting at edge of plate, lb/in. of circumference
M	= radial moment acting at edge of plate, in.-lb/in. of circumference
W	= total ring load acting on plate (Fig. A-8132.2-1), lb
ν	= Poisson's ratio
E	= Young's modulus for plate material, psi
E_t	= Young's modulus for tube material, psi
T_m	= mean temperature averaged through the thickness of the plate, °F
T_s	= temperature of the surface of the plate, °F
α	= coefficient of thermal expansion, in./in.-°F
t_t	= tube wall thickness, in.
p_s	= pressure on surface where stress is computed, p_1 or p_2 , psi
p_i	= pressure inside tubes, psi
$\ln$	= $\log_e$
c	= radius of ring load (Fig. A-8132.2-1), in.
x	= axis of symmetry of hole pattern through the smaller ligament thickness (Figs. A-8142-3 through A-8142-5)
y	= axis of symmetry of hole pattern, perpendicular to x axis

FIG. A-8120-1

FIG. A-8120-1

A-8130 ANALYSIS OF CIRCULAR PERFORATED AREA

[98]

A-8131 Procedure

(a) The analysis method for perforated plates presented in this Article utilizes the concept of the equivalent solid plate. In this method, the perforated plate is replaced by a solid plate which is geometrically similar to the perforated plate but has modified values of the elastic constants.

(b) The elastic modulus E and Poisson's ratio ν are replaced by the effective elastic modulus E^* and effective Poisson's ratio ν^* of the perforated plate, and conventional equations for plates are used to determine the deformations and nominal stresses for the equivalent solid plate. The deformations so computed may be used directly in evaluating interaction effects. The actual values of the stress intensities in the perforated plate are determined by applying multiplying factors to the nominal stresses computed for the equivalent solid plate.

(c) The effective elastic constants are functions of the ligament efficiency η . The values are given in Fig. A-8131-1 for the range of $0.05 \leq \eta \leq 1.0$ in the form of ν^* vs. η for a material with $\nu = 0.3$, and E^*/E vs. η . The stress multipliers are given in Figs. A-8142-1 through A-8142-6. The Y factors presented in Figs. A-8142-3 and A-8142-4 represent the largest values occurring through the thickness at the given angular position.

(d) The region of the perforated plate outside the effective radius R^* is called the plate rim. This unperforated portion of the plate may be considered as a separate connecting member, a ring or cylinder, and the structure may be analyzed in accordance with the procedures of A-6000.

[98]

A-8132 Analysis of Equivalent Solid Plate

In the following subparagraphs, equations are given for the nominal stresses and edge displacements for the equivalent solid circular plate under various axisymmetric load conditions.

A-8132.1 Edge Loads (See Fig. A-8132.1-1)

(a) Stresses at any location on the surface of the equivalent solid plate.

$$\sigma_r = \sigma_\theta = \frac{Q}{t} \pm \frac{6M}{t^2} \quad (1)$$

(1)

When double signs are used, the upper sign applies to the top surface as shown in Fig. A-8132.1-1.

(b) Edge displacements of midplane at R^* :

$$w = \frac{R^*}{E^*t} (1 - \nu^*) Q \quad (2)$$

$$\theta = - \frac{12R^*}{E^*t^3} (1 - \nu^*) M \quad (3)$$

(2 - 3)

FIG. A-8131-1

FIG. A-8131-1

A-8132.2 Ring Loads Transverse to the Plane of the Plate (See Fig. A-8132.2-1)

(a) Stresses at any radial location r on the surfaces of the equivalent solid plate: for $r \leq c$,

$$\sigma_r = \sigma_\theta = \pm \frac{3W}{2\pi t^2} \left[\frac{1}{2} (1 - \nu^*) - \frac{1}{2} (1 - \nu^*) \times \left(\frac{c}{R^*} \right)^2 + (1 + \nu^*) \ln \frac{R^*}{c} \right] \quad (4)$$

(4)

for $r > c$,

$$\sigma_r = \pm \frac{3W}{2\pi t^2} \left[\frac{1}{2} (1 - \nu^*) \left(\frac{c}{r} \right)^2 - \frac{1}{2} (1 - \nu^*) \times \left(\frac{c}{R^*} \right)^2 + (1 + \nu^*) \ln \frac{R^*}{r} \right] \quad (5)$$

$$\sigma_\theta = \pm \frac{3W}{2\pi t^2} \left[(1 - \nu^*) - \frac{1}{2} (1 - \nu^*) \left(\frac{c}{r} \right)^2 - \frac{1}{2} (1 - \nu^*) \times \left(\frac{c}{R^*} \right)^2 + (1 + \nu^*) \ln \frac{R^*}{r} \right] \quad (6)$$

(5 - 6)

(b) Edge displacements of midplane at $r = R^*$:

$$(7) w = 0$$

$$\theta = \frac{3R^*}{\pi E^* t^3} (1 - \nu^*) \left[1 - \left(\frac{c}{R^*} \right)^2 \right] [W] \quad (8)$$

(8)

A-8132.3 Uniformly Distributed Pressure Loads (See Fig. A-8132.3-1)

(a) Stresses at any location r on the surfaces of the equivalent solid plate:

$$\sigma_r = \pm \frac{3}{8} \left(\frac{R^*}{t} \right)^2 (3 + \nu^*) \left[1 - \left(\frac{r}{R^*} \right)^2 \right] [\Delta p] \quad (9)$$

$$\sigma_\theta = \pm \frac{3}{8} \left(\frac{R^*}{t} \right)^2 \left[(3 + \nu^*) - (1 + 3\nu^*) \left(\frac{r}{R^*} \right)^2 \right] [\Delta p] \quad (10)$$

(9 - 10)

(b) Edge displacement of midplane at $r = R^*$:

$$w = \frac{\nu R^*}{E} \left(\frac{p_1 + p_2}{2} \right) \quad (11)$$

$$\theta = \frac{3}{2} \frac{(R^*)^3}{E^* t^3} (1 - \nu^*) [\Delta p] \quad (12)$$

(11 - 12)

A-8132.4 Pressure in Tubes or Perforations (See Fig. A-8132.4-1)

(a) Stresses at any location in the equivalent solid plate:

$$\sigma_r = \sigma_\theta = \frac{h}{P} \frac{(P - h - 2t_f)}{\left[h + 2 \left(\frac{E_f}{E} \right) t_f \right]} p_i \quad (13)$$

(13)

(b) Edge displacements of midplane at $r = R^*$:

$$w = \frac{R^*}{E} \left[\frac{E}{E^*} (1 - \nu^*) - (1 - \nu) \right] p_i \quad (14)$$

(14)

where E^*/E and v^* should be evaluated for the ligament efficiency:

$$\frac{h}{P} = \frac{h + (2E_t/E)t_t}{P} \quad (15)$$

(15)

using Fig. A-8131-1;

$$\theta = 0$$

A-8140 STRESS INTENSITIES AND STRESS LIMITS FOR PERFORATED PLATES

A-8141 Equations for Stress Intensities

In A-8140 equations are given for the stress intensities in a perforated plate using the stresses determined for the equivalent solid plate.

Page 228

FIG. A-8132.1-1

FIG. A-8132.1-1

FIG. A-8132.2-1

A-8142 Typical Ligaments in a Uniform Pattern**A-8142.1 Mechanical and Pressure Loads on Circular Plates**

(a) The stress intensity based on stresses averaged across the minimum ligament width and through the thicknesses of the plate is limited according to NB-3221.1 and is computed from the larger of:

$$S = \frac{P}{h} \sqrt{\left(\frac{\Delta p R^*}{t} + \frac{W}{\pi t R^*}\right)^2 + (\bar{\sigma}_r)^2} \quad (16)$$

(16)

or

$$S = \frac{1}{2} \frac{P}{h} \left[\sqrt{\left(\frac{\Delta p R^*}{t} + \frac{W}{\pi t R^*}\right)^2 + (\bar{\sigma}_r)^2} + \bar{\sigma}_r + (2p_i h/P) \right] \quad (17)$$

(17)

where only the positive root is used. The first term under the radical reflects the effect of the transverse shear stress due to the mechanical and pressure loads. It is a maximum in the outermost ligament of the perforated region, but it may be determined for any radius, larger than c , by substituting r for R^* in the expression. For $r < c$, the $W/\pi t R^*$ term should be omitted. $\bar{\sigma}_r$ is the stress resulting from applied in-plane loading averaged through the thickness of the equivalent solid plate. It includes the stresses due to pressure in the tubes or perforations given in A-8132.4. No bending stresses are included.

(b) The stress intensity based on stresses averaged across the minimum ligament width but not through the thickness of the plate is limited according to NB-3221.3 and is computed from

$$(18) S = K (P/h) \sigma_{ave}$$

where

K

= stress multiplier from Fig. A-8142-1

σ_{ave}

= larger value of σ_r or σ_θ , psi, caused by mechanical loading and structural interaction with adjacent members, computed as the sum of the surface stresses in the equivalent solid plate, using the applicable formulas in A-8130

However, supporting interactions from adjacent members may only be considered if the primary plus secondary stresses in such members are limited to $1.5S_m$. Effects of temperature are not included.

A-8142.2 Combined Mechanical and Thermal Effects

(a) The range of the stress intensity based on stresses averaged across the minimum ligament width but not through the thickness of the plate is limited according to NB-3222.2 and is computed from

$$(19) S = K (P/h) \sigma_I$$

where

K

= stress multiplier from Fig. A-8142-1

σ_I

= larger absolute value of σ_r or σ_θ , psi, caused by mechanical loading or structural interaction with adjacent members, computed as the sum of the surface stresses in the equivalent solid plate using the applicable equations in A-8130 and A-8150

The effects of temperature are included in the consideration of the structural interaction with adjacent members.

(b) The peak stress intensity due to all loadings is limited by cumulative fatigue considerations as described in NB-3222.4 and is given by:

$$(20) S = Y_{\max} (P/h) \sigma_I + p_s$$

FIG. A-8132.3-1

FIG. A-8132.3-1

FIG. A-8132.4-1

FIG. A-8132.4-1

where

p_s

= pressure on the surface where the stress is being computed, psi

σ_1

= principal stress being the largest absolute value in the plane of the equivalent solid plate, psi

σ_2

= principal stress having the smallest absolute value in the plane of the equivalent solid plate, psi (Equivalent solid plate stresses due to various loads shall be superimposed in order to obtain σ_1 and σ_2 before any multipliers are applied, and the signs of σ_1 and σ_2 should be maintained.)

$Y_{\max}$

= stress multiplier given in Fig. A-8142-2 as a function of the biaxiality ratio $\beta = \sigma_2/\sigma_1$

The solid curves in Fig. A-8142-2 give the maximum stress multipliers for the worst angular orientation of σ_1 and σ_2

with respect to the axes of symmetry x and y of the hole pattern. In some cases, the worst orientation may not exist anywhere in the plate, and the use of lower stress multipliers is justified. An important case concerns the thermal stress produced by a temperature gradient across the diametral lane in a perforated plate. Such a gradient causes a uniaxial stress oriented parallel to the diametral lane. If the diametral lane is parallel to the y axis as shown in Fig. A-8142-3, the stress multiplier given by the dashed line in Fig. A-8142-2 may be used.

FIG. A-8142-1

FIG. A-8142-1

(c) Equation (20) will give the maximum stress intensity for any loading system. Equation (20) is not adequate for more complex cyclic histories where the angular orientation of the maximum stress intensity varies during the cycle. In such cases, it is necessary to compute the stress history at each angular orientation ϕ using Eq. (21):

$$(21) S_{\phi} = Y_1(P/h)\sigma_1 + Y_2(P/h)\sigma_2 + p_s$$

where

S_{ϕ}

= peak stress intensity at the angular orientation ϕ

Y_1, Y_2

= stress multipliers in Figs. A-8142-3 through A-8142-5 for various orientations of the principal stresses σ_1 and σ_2 computed for the equivalent solid plate

FIG. A-8142-2

FIG. A-8142-2

Note that these figures give stress multipliers for particular angular orientation only. The graph for the angular orientation closest to the actual angular orientation should be used. This is sufficiently accurate since the maximum possible difference between the actual orientation and the nearest orientation given in Figs. A-8142-3 through A-8142-5 is only 7.5 deg. Examples for the computation of S_ϕ are given as follows.

Example 1

The combined stresses in the equivalent solid plate for a perforated plate of 0.05 ligament efficiency were computed at a point as:

$$\sigma_r = 750 \text{ psi}$$

$$\sigma_\theta = -1100 \text{ psi}$$

and σ_r is rotated 12 deg., measured from the y axis of the hole pattern. To determine the value of σ_ϕ at 40 deg. from the y axis, use the following procedure: let $\sigma_1 = \sigma_r$, $\sigma_2 = \sigma_\theta$. Since the angular orientation of 12 deg. is closest to 15 deg., use Fig. A-8142-5 for the stress multipliers. Read at $\phi = 40$ deg. on Scale A: $Y_1 = +1.65$; on Scale B: $Y_2 = -0.70$. Then from Eq. (21) in (c) above, the peak stress intensity is computed as:

$$\begin{aligned} S_\phi &= \frac{1}{0.05} (+1.65)(750) + \frac{1}{0.005} (-0.70)(-1100) \\ &= 40,200 \text{ psi} \end{aligned}$$

Example 2

For the same plate as above at another point, the direction of σ_r coincides with the x axis. Let $\sigma_r = \sigma_2$, $\sigma_\theta = \sigma_1$. Read at $\phi = 40$ deg. from Fig. A-8142-3, $Y_1 = +2.75$ and from Fig. A-8142-4, $Y_2 = -1.80$. Then

$$S_{\phi} = \frac{1}{0.05} (2.75)(-1100) + \frac{1}{0.05} (-1.80)(750)$$

$$= -87,500 \text{ psi}$$

(d) The peak stress intensity at the outermost hole is computed from:

$$(22) S = K_r \sigma_{\text{rim}} + p_s$$

where

K_r

= a stress multiplier from Fig. A-8142-6

σ_{rim}

= the nominal circumferential stress in the rim, psi

The stresses given by Eqs. (20) and (21) in (b) and (c) above and by Eq. (22) are limited by cumulative fatigue considerations, as described in NB-3222.4.

A-8143 Irregular Ligament Patterns or Thin Ligaments in a Nominally Uniform Pattern

For irregular ligament patterns or thin ligaments in a nominally uniform pattern, the stresses are determined as given in the following subparagraphs.

A-8143.1 Average Stress Intensity.

The stress intensity based upon the ligament stresses averaged across the ligament width and through the plate thickness due to pressure plus other mechanical loads is limited to $3.0S_m$ in accordance with Table NB-3217-1. The appropriate value is computed according to A-8142.1(a), where h_a (the actual width of the thin ligament) is used in place of the nominal width h .

FIG. A-8142-3

FIG. A-8142-3

FIG. A-8142-4

FIG. A-8142-4

FIG. A-8142-5

FIG. A-8142-5

FIG. A-8142-6

FIG. A-8142-6

A-8143.2 Peak Stress Intensity.

The peak stress intensity in the thin ligament due to mechanical loading and structural interaction with adjacent members, including thermal effects, is limited by cumulative fatigue considerations. This peak stress intensity is computed by multiplying the peak stress intensity for a nominal thickness ligament by the K_m value given in Fig. A-8143.2-1.

(a) The peak stress intensity in nominal ligament is calculated as indicated in A-8142.2(b).

A-8150 THERMAL SKIN EFFECT

A-8151 General Considerations

In certain cases, the temperature gradient through the thickness of a perforated plate can be closely approximated by a step change in the metal temperature near the surface of the plate. In such a case, significant thermal stresses develop only in the skin layer of the plate at the surface where the temperature change occurs and the thermal stresses in the remainder of the plate are negligible.

A-8152 Maximum Thermal Skin Stress

The maximum thermal skin stress on the surface of a perforated plate can be computed from the relation:

$$\sigma_{\text{skin}} = K_{\text{skin}} Y_{\text{max}} \left(\frac{P}{h} \right) \left(\frac{E\alpha}{1 - \nu} \right) (T_m - T_e) \quad (23)$$

(23)

where

E, α, ν	= modified material properties
Y_{max}	= stress multiplier from Fig. A-8142-2, for $\beta = +1$
T_m	= mean temperature of the plate, °F
T_s	= temperature of the plate at the surface under consideration, °F
P	= pitch
h	= ligament width, in.

A-8153 Peak Stress Intensities When Thermal Skin Stresses Are Included

(a) When thermal skin stresses are to be combined with other stresses to obtain the peak stress intensity, Eq. (23) of A-8152 may not be used. In such a case the thermal stresses at any location on the surface of the equivalent solid plate are given by:

$$\sigma_r = \sigma_\theta = K_{\text{skin}} \frac{E\alpha}{1 - \nu} (T_m - T_s) \quad (24)$$

(24)

where

K_{skin}

= stress ratio from Fig. A-8153-1

T_m

= mean temperature of the plate, °F

T_s

= surface temperature of the plate, °F

E, ν

= unmodified material properties (since K_{skin} includes the consideration for E^* and ν^*)

(b) The equivalent solid plate stresses given by Eq. (23) can then be combined with other solid plate stresses and the method given in A-8142.2(b) can be used to obtain the peak stress intensity.

Page 236

FIG. A-8153-1

ARTICLE A-9000 INTERACTION METHOD

A-9100 INTRODUCTION

A-9110 SCOPE

(a) This Article contains a method for evaluating the adequacy of linear structural elements under combined loads, without determining principal stresses, by use of the stress ratio/interaction curve method. By using an interaction formula for combined stress states the ability of a linear structural element to withstand combined loads can then be determined provided the strength of the element under each individual load is known. The method can be applied to elastic and inelastic problems, including elastic and inelastic stability, and is useful when an exact stress analysis is not practical.

(b) A general interaction formula for three states of stress is given by the following:

$$(1) R_1^p + (R_2^q + R_3^r)^s \leq 1.0$$

where R_1 , R_2 , and R_3 are ratios of either individual stresses, stress resultants, or loads to their respective allowables; and the exponents p , q , r , and s constitute the interaction relationship. These exponents are based upon experimental and/or theoretical considerations. Generally speaking, such an interaction is set up for each individual element in a structure (each beam, column, etc.), and each element will have its own set of exponents for the loads to which it is subjected.

(c) For elastic analysis of compact structures (those in which buckling need not be considered), interaction methods can be used to determine the yield surface. However, classical strength of material methods can also be used to obtain principal stresses, hence an interaction method is not of importance. For ultimate strength, an exact stress analysis is frequently impractical and interaction methods provide a useful alternative. In addition, for structures subject to more than one type of load which can cause instability (e.g., torsional and axial buckling of thin-walled tubes or pipes), interaction methods can again be used.

A-9120 NOMENCLATURE

(a) The definitions of the symbols used in this Article are given below.

A	= cross-sectional area, sq in.
c	= distance from neutral axis to outermost fiber, in.
e	= strain, ksi
f_{ap}	= linearized allowable bending stress (apparent stress), ksi
f_{uk}	= linearized ultimate bending stress, ksi, for section factor K
f_{yk}	= linearized yield bending stress, ksi, for section factor K
I	= moment of inertia, in. ⁴
K	= section factor
m	= applied moment, in.-lb
M	= allowable bending moment, in.-lb
n	= interaction exponent
P	= axial load, lb
Q_m	= first moment of the area between the neutral axis and outer fiber

$$= \int_0^c y da$$

R	= ratio of an individual stress or load to its allowable
S	= stress, ksi
S_o	= trapezoidal intercept stress, ksi
U	= stress field utilization factor
x	= centroidal axis, x direction
x'	= principal axis, x' direction
y	= centroidal axis, y direction
y'	= principal axis, y' direction
y_p	= distance from principal axis to intermediate fiber, in.
ϕ	= angle between centroidal and principal axis, deg.
γ	= plasticity factor

(b) The indices used with the symbols in this Article are defined below.

Page 239

al	= allowable
ap	= apparent
b	= bending
bc	= buckling
c	= compression
pl	= proportional limit
s	= shear
t	= tension
to	= torsion
u	= ultimate
y	= yield
1, 2	= locations across a section

A-9200 INTERACTION EQUATIONS

A-9210 SCOPE

- (a) This Subarticle provides interaction equations based on experimental data for a number of common structural shapes.
- (b) Allowable loads and stresses for the interaction equations presented herein shall be determined in accordance with A-9300.
- (c) Interaction equations for combinations of loads other than those specified herein may be used, provided they are developed in accordance with the rules of A-9400.
- (d) Interaction equations, which may be used for common beam shapes subject to various combinations of loads, are presented in Table A-9210(d)-1. As an alternative to some of the interaction equations given in Table A-9210(d)-1, the curve in Fig. A-9210(d)-1 may be used.
- (e) All structural shapes subject to buckling shall be governed by the requirements of NF-3300.
- (f) Interaction equations which may be used for thin- and thick-walled tubes and pipes, subject to various combinations of loads, are presented in Table A-9210(f)-1 (in the course of preparation).
- (g) Interaction equations which may be used for flat, unperforated plates, subject to various combinations of loads, are presented in Table A-9210(g)-1 (in the course of preparation).

A-9300 ALLOWABLE LOADS AND STRESSES

[98]

A-9310 SCOPE

This Subarticle provides criteria for determining the allowable loads for components or supports subject to the application of one or more loads. The allowable loads are to be based on the allowable stresses set forth in F-1331.2 or F-1341.5, as appropriate, for either elastic or plastic system analysis.

[98]

[98]

A-9311 Material Properties

The material properties used in developing the allowable component or support loads or stresses shall be based on Section II, Part D, Subpart 1, and included and justified in the Design Report.

[98]

A-9312 Strain Rate Effects

Strain rate effects on material properties may be considered if justified in the Design Report.

A-9313 Temperature Effects

Temperature effects on the allowable component or support loads or stresses shall be considered and justified in the Design Report.

[98]

A-9314 Allowable Load

The allowable load of a component or support is defined as the lesser of (a) through (d) below.

- (a) The load at which the most severely stressed fiber reaches the allowable stress defined in F-1331.2 or F-1341.5, as appropriate.

(b) The load at which either strain or deformation exceeds the limits provided by the component or support Design Specification.

(c) The load at which loss of component or support function occurs, as defined by the component or support Design Specification.

(d) The allowable buckling load as defined in F-1370(c).

[98]

A-9320 METHOD

(a) The allowable load of a component or support under the application of a single load may be determined by experimental or analytical methods or both. The allowable loads of a component or support thus determined are to be modified by the effects discussed in A-9312 and A-9313 for use in the interaction equations of A-9200.

(b) An acceptable method of determining the allowable loads of beam shapes in pure bending or in bending

Page 240

in combination with direct loads and shear is the apparent stress method provided in A-9500.

**TABLE A-9210(d)-1
INTERACTION EQUATIONS FOR COMMON BEAM SHAPES**

Type of Load	Interaction Equation ^{2,3}	Remarks
Simple bending	$R_b < 1$	$R_b = m/M$
Complex bending	$R_{bx'} + R_{by'} < 1$	$R_{bx'} = m_x'/M_{x'}$, etc.
Simple shear	$R_s < 1$	$R_s = S_s/S_{sal}$
Complex shear	$\sqrt{R_{sx'}^2 + R_{sy'}^2} < 1$	$R_{sx'} = S_{sx'}/S_{sal}$, etc.; $S_{sx'}$ and $S_{sy'}$ are maximum shear stresses
Simple bending plus shear	$\sqrt{R_b^2 + R_s^2} < 1$	Note (1)
Complex bending plus shear	$\sqrt{R_{bx'}^2 + R_{by'}^2 + R_s^2} < 1$	$R_{bx'} = R_{bx'} + R_{by'}$; R_s = $\sqrt{R_{sx'}^2 + R_{sy'}^2}$; Note (1)
Simple or complex bending plus tension	$R_b' + R_t^n < 1$	$R_t = P_t/P_{tal}$; to determine n use A-9532
Simple or complex bending tension and shear	$\sqrt{(R_b' + R_t^n)^2 + R_s^2} < 1$	Note (1); to determine n use A-9532; see A-9533
Simple or complex bending and compression	$R_b' + R_c < 1$	Notes (1) and (4); $R_c = P_c/P_{cal}$
Simple or complex bending compression and shear	$\sqrt{(R_b' + R_c)^2 + R_s^2} < 1$	Notes (1) and (4); see A-9535

NOTES:

- (1) As an alternate to the given interaction equation, the curve of Fig. A-9210(d)-1 may be used.
- (2) Allowable loads for use in interaction equations should be based on allowable stresses as defined in A-9300.
- (3) All interaction ratios R_i are positive by definition.
- (4) Amplification of bending moment by axial load shall be taken into account.

TABLE A-9210(d)-1 INTERACTION EQUATIONS FOR COMMON BEAM SHAPES

FIG. A-9210(d)-1 INTERACTION CURVE FOR BEAMS SUBJECT TO BENDING AND SHEAR OR TO BENDING, SHEAR, AND DIRECT LOADS

FIG. A-9210(d)-1 INTERACTION CURVE FOR BEAMS SUBJECT TO BENDING AND SHEAR OR TO BENDING, SHEAR, AND DIRECT LOADS

(c) An acceptable method of determining the allowable loads of pipes and tubes in pure bending or in bending in combination with direct loads and shear is provided in A-9600 (in the course of preparation).

A-9400 NEW INTERACTION EQUATIONS

A-9410 SCOPE

Interaction equations other than those provided in A-9200 may be used for the analysis of components or supports, provided they are developed in accordance with the rules of this Section.

A-9420 METHOD

Any new interaction equations to be used shall be included and justified in the Design Report. They may be justified by one of the following:

- (a) common appearance in appropriate technical literature or in industry codes or standards;
- (b) experimental development which includes a variation of all types of loads or stresses that appear in the interaction equations. Such a load or stress variance shall bound the loads or stresses to which the component is subjected;
- (c) theoretical development which includes testing to verify the interaction equations developed.

A-9500 DETERMINATION OF ALLOWABLE BENDING STRENGTH OF BEAMS BY THE APPARENT STRESS METHOD

A-9510 SCOPE

(a) This Subarticle provides a method to calculate the strength of beams in the plastic range under pure bending or under bending combined with direct loads and shear. It is based on the work of Cozzone^{1,2} and utilizes a fictitious stress called an *apparent stress*. This method shall not be used for the analysis of thin-walled tubes or pipes.

(b) The conventional beam theory, based on the assumption that a plane section before bending remains plane after bending, gives a linear distribution of strain and stress in the elastic range up to the proportional limit. Beyond the proportional limit, however, although the strain distribution is assumed to remain linear, the stress distribution corresponds with the stress-strain relationship for the material. An approximation of this distribution has been obtained, which enables the prediction of the effects of shape and material properties on bending in the plastic range. This method has the advantage that strain hardening may be taken into account.

(c) The methods provided herein may also be used for the analysis of beams with cutouts or notches, provided that the geometric properties are based on the net area at the cutout or notch.

(d) The effect of cyclic loading should be evaluated independently, where appropriate.

A-9520 SIMPLE BENDING

[98]

A-9521 Simple Bending - Symmetrical Sections

(a) The method given below may be used when the resultant applied moment vector is parallel to a principal axis which is also an axis of symmetry.

FIGURE - UNTITLED

(b) The section factor K is given by the formula $K = 2Q_m/(I/c)$. If $K > 2.0$, use $K = 2.0$. Section factors are given in Table A-9521(b)-1 for common structural shapes.

(c) The allowable bending moment shall be determined as given in (1) through (3) below.

(1) Using the method outlined in A-9540, derive the relationship between the allowable stress S_{al} and the linearized allowable stress f_{ap} for the proper section factor K . An example calculation for SA-672 A50 material at 600°F is provided in A-9542, with the resulting relationship shown in Fig. A-9542-1.

(2) Using the value of S_{al} set forth in F-1323.3 or F-1324.3, as appropriate, determine the value of f_{ap} for the proper K .

(3) Multiply f_{ap} from (2) above by I/c to obtain the allowable moment M .

[98]

**TABLE A-9521(b)-1
SECTION FACTORS**

Flanges Only			Solid Round

TABLE A-9521(b)-1 SECTION FACTORS

A-9522 Simple Bending - Unsymmetrical Section

(a) Use the following method when the resultant applied moment vector is parallel to a principal axis which is not an axis of symmetry.

FIGURE - UNTITLED

(1) Break the section down into the two parts on either side of the principal axis. For each part, compute $Q_m I$, and I/c about the principal axis of the original complete section.

(2) Compute $K = Q_m / (I/c)$ for each part. In utilizing the K value for each part, computed as above, it will be the same as for a symmetrical section composed of the given part and its reflection about the principal axis of the original section.

(b) The allowable bending moment shall be determined as given in (1) through (4) below.

(1) Use the method given in A-9521(c) and the K value of the part with the larger c to obtain an f_{ap} value for this part.

(2) Determine the strain e_{ap} associated with S_{al} from the engineering stress-strain curve.

(3) Obtain the allowable maximum strain e_1 in the part having the smaller c by the following equation:

$$e_1 = (\text{smaller } c / \text{larger } c) e_{ap}$$

Enter this strain e_1 on the stress-strain curve and obtain the corresponding stress from the stress-strain curve. Use this stress value as the allowable stress S_{al} and, with the K value for the part with the smaller c , use the method of A-9521(c) to obtain f_{ap} for this part.

(4)

NOTE: Moment vectors are designated by double-headed arrows and are to be interpreted by the left-hand rule: point left thumb in direction of vector and natural curl of fingers will designate the direction of moment.

FIG. A-9523.1-1 SIGN CONVENTION AND NOMENCLATURE

A-9523.1-1 SIGN CONVENTION AND NOMENCLATURE

A-9523 Complex Bending - Symmetrical and Unsymmetrical Sections

This condition occurs when the resultant applied moment vector is not parallel to a principal axis.

A-9523.1 Sign Convention and Nomenclature.

In Fig. A-9523.1-1, let x and y represent two mutually perpendicular centroidal axes, and let x' and y' represent the principal axes.

[98]

A-9523.2 Resolution of Complex Bending Into Simple Bending.

Any case of complex bending may be resolved into two cases of simple bending about the principal axes of the section. The principal axes are defined as mutually perpendicular centroidal axes

Page 243

about which the moments of inertia are a maximum and minimum, respectively, and about which the product moment of inertia is zero. The procedure is given in (a) through (d) below.

(a) Determine the principal axes x' and y' . If they cannot be determined by inspection, obtain $I_{x'}$, $I_{y'}$, and I_{xy} about any arbitrary pair of centroidal axes.

$$\tan 2\phi = 2I_{xy}/(I_y - I_x)$$

(b) Using the x' axis as a reference, determine the allowable moment $M_{x'}$ as described under simple bending (A-9521 and A-9522).

(c) Using the y' axis as a reference, determine the allowable moment $M_{y'}$ as described under simple bending (A-9521 and A-9522).

(d) For use in the interaction equations of A-9210, moments in the global axis shall be resolved into moments about the principal axes by use of the following relationships:

$$m_{x'} = m_x \cos \phi + m_y \sin \phi$$

$$m_{y'} = m_x \sin \phi + m_y \cos \phi$$

[98]

A-9530 BENDING COMBINED WITH A STRESS FIELD

[98]

A-9531 Interaction - Simple or Complex Bending and Shear

The maximum shear stress in a beam usually occurs at the principal (neutral) axis where the bending stress is zero. The maximum bending stress occurs at an extreme fiber where the shear stress is usually zero.

(a) In the elastic range, the distribution of shear and bending stresses (see Fig. A-9531-1) is usually such that the most critical point in the section is at either the principal axis or the extreme fiber. This is true on a rectangular section since the shear distribution across the section is parabolic and the bending distribution is linear. If the shear distribution has been elliptical, every point in the cross section will be equally critical in combined stress based on circular interaction.

(b) In the plastic range, however, the distribution of the shear stress as well as the bending stress differs from that in the elastic range. This results in intermediate points which frequently become more critical in combined stress than either the shear stress at the principal axis or the bending stress at the extreme fiber.

FIG. A-9531-1 BENDING AND SHEAR STRESSES

FIG. A-9531-1 BENDING AND SHEAR STRESSES

(c) To find the most critical point would require the calculation of combined stresses at a series of points across the section. This procedure would not only be laborious but probably incorrect in the conservative direction, since there would undoubtedly be some redistribution of stress away from the most critical point, although the exact nature of this redistribution appears to be extremely difficult to determine. Therefore, the procedure of (1) through (4) below shall be used.

(1) The method used to determine the shear flows for simple or complex bending shall be included and justified in the Design Report.

(2) For complex bending, the maximum principal shear stresses S_{sx} and S_{sy} shall be determined for use in the interaction equations of A-9210.

(3) For simple or complex bending, the allowable shear stress S_{sal} shall be taken as $0.6S_{tal}$.

(4) The allowable moments shall be determined as in A-9521 or A-9522, as appropriate.

[98]

A-9532 Interaction - Simple or Complex Bending and Tension

(a) The allowable moments for simple or complex bending shall be determined from A-9521 or A-9522, as appropriate.

(b) The allowable tensile load P_{al} shall be taken as AS_{al} .

(c)

(c) The interaction exponent n for use in the interaction equations of A-9210(d) shall be determined from (1) through (3) below.

(1) Determine $Ac/2Q_m$ for use in obtaining the interaction exponent. If the section is unsymmetrical, take c for the side for which axial and bending stresses are of opposite sign. For complex bending, obtain both $Ac/2c_x$ and $Ac/2c_y$. In obtaining $Ac/2c_x$ if the section

Page 244

is unsymmetrical about the x' axis, take c_x for the side for which axial stress and stress due to m_x are of opposite sign. Obtain $Ac/2c_y$ in the same manner.

FIG. A-9532(c)(3)-1 INTERACTION EXPONENT

FIG. A-9532(c)(3)-1 INTERACTION EXPONENT

(2) The material plasticity factor for use in obtaining the interaction exponent is $\gamma = 0.90$ for all materials.

(3) Using $Ac/2Q_m$ determined above in (1) and γ determined above in (2), obtain n from Fig. A-9532(c)(3)-1. To determine the interaction exponent for complex bending, obtain both n_x and n_y from Fig. A-9532(c)(3)-1 and determine a combined n using $n = (n_x R_{bx'} + n_y R_{by'}) / R_b$

A-9533 Interaction - Simple or Complex Bending, Tension, and Shear

When bending acts in addition to tension and shear, allowables shall be determined as provided in (a) through (c) below.

(a) Follow the procedure outlined in A-9531 and A-9532 to obtain S_{ab} , P_{ab} , M_x , M_y , and n .

(b) Plot the curve of $R_b + R_t^n = 1$ [Fig. A-9533(b)-1] and the intersection of R_b and R_t . Call this point A. Obtain $a = \overline{OA}$ and $b = \overline{OB}$.

(c) Obtain the bending-tension utilization factor for use in Fig. A-9210(d)-1:

$$U = a/b$$

A-9534 Interaction - Simple or Complex Bending and Compression

(a) When compression acts in addition to simple or complex bending, the applied moment m shall take into account the additional bending caused by the compressive load.

(b) The allowable moments for simple or complex bending shall be determined from A-9520, as appropriate.

(c) The allowable compressive load P_{cal} shall be taken as the lesser of AS_{al} and the allowable buckling load [F-1370(c)].

[98]

A-9535 Interaction - Simple or Complex Bending, Compression, and Shear

When bending acts in addition to compression and shear, the following procedure may be used to determine the interaction relationships for use in A-9210.

(a) Follow the procedure in A-9534 to obtain the applied and allowable moments and the allowable compressive load.

(b) Obtain the bending-compression utilization factor $U_{bc} = R_b + R_c$.

(c) U_{bc} may be used in Fig. A-9210(d)-1 by replacement of U_{bt} by U_{bc} .

[98]

Page 245

FIG. A-9533(b)-1 INTERACTION CURVE FOR BENDING AND TENSION

FIG. A-9533(b)-1 INTERACTION CURVE FOR BENDING AND TENSION

A-9540 PROCEDURE FOR DETERMINATION OF ALLOWABLE BENDING STRESS

[98]

A-9541 Derivation of Linearized Allowable Bending Stress for Any Material

A fictitious bending stress, called the linearized allowable bending stress f_{ap} , may be used for establishing the bending strength of a material. This method assumes that in the plastic region the nonlinear stress-strain relationship for a particular section and material can be approximated by a trapezoidal shape as shown in Fig. A-9541-1.

The stress S_o is a fictitious stress which is assumed to exist at the neutral axis or at zero strain. The value of S_o is determined by requiring that the internal moment of the engineering stress-strain curve must equal the internal moment of the assumed trapezoidal shape. Thus, the total moment capacity of a symmetrical section may be expressed as follows:

$$\begin{aligned}
 M &= 2S_o \int_0^c y da + (S_{al} - S_o)(I/c) \\
 &= 2S_o Q_m + (S_{al} - S_o)(I/c) \\
 &= (I/c) \{ S_{al} + S_o [2Q_m / (I/c) - 1] \} \\
 &= (I/c) [S_{al} + S_o (K - 1)] \quad (2)
 \end{aligned}$$

(2)

Thus, the linearized allowable stress for any section factor K becomes

$$(3) f_{apk} = S_{al} + (K - 1)S_o$$

and the moment capacity of the section is as follows:

$$(4) M = f_{apk} I/c$$

An alternate method of determining f_{ap} for any section factor is to express it in terms of the linearized allowable bending stress for a 1.5 stress factor:

$$(5) f_{apk} = f_{ap1.5} + (K - 1.5)S_o$$

When the allowable stress S_{al} is equal to the ultimate stress S_y , Eqs. (3) and (5) become

$$(6) f_{uk} = S_u + (K - 1)S_{ou}$$

$$(7) f_{uk} = f_{u1.5} + (K - 1.5)S_{ou}$$

When the allowable stress S_{al} is equal to the yield stress S_y , Eqs. (3) and (5) become

$$(8) f_{yk} = S_y + (K - 1)S_{oy}$$

$$(9) f_{yk} = f_{y1.5} + (K - 1.5)S_{oy}$$

where S_{ou} and S_{oy} are the trapezoidal intercept stresses corresponding to S_u and S_y .

FIG. A-9541-1 TRAPEZOIDAL STRESS-STRAIN RELATIONSHIP

FIG. A-9541-1 TRAPEZOIDAL STRESS-STRAIN RELATIONSHIP

In order to calculate the allowable moment of a given beam cross section by the use of Eqs. (3) and (4), the intercept stress S_o must first be determined using the allowable moment, determined either by test or an exact stress analysis, that corresponds to a known value of K . Such effort would negate the advantage of this method. On the other hand, the values of S_{ou} and S_{oy} have been calculated for about 50 materials³ and are shown in Fig. A-9541-2. These curves may be utilized for the carbon, low, and high alloy steels given in Section II, Part D, Subpart 1. The corresponding values of $f_{u1.5}$ and $f_{y1.5}$ are shown in Fig. A-9541-3.

Once f_{uk} and f_{yk} are determined from Fig. A-9541-3 and Eqs. (6)-(9), f_{ap} for any value of the allowable stress S_{al} may be

determined as shown in (a) through (c) below.

(a) For $S_{al} \leq S_{pl}$, where S_{pl} is the proportional limit stress (Fig. A-9541-4),

$$(10) f_{apk} = S_{al}$$

3Gavalis, R. Bending Strength in the Plastic Range. Machine Design, July 1964.

FIG. A-9541-4 PROPORTIONAL LIMIT AS A FUNCTION OF YIELD STRESS

(b) For $S_{pl} \leq S_{al} \leq S_y$

$$(11) f_{apk} = S_{pl} + Z_{1k}(S_{al} - S_{pl})$$

where

$$(12) Z_{1k} = (f_{yk} - S_{pl}) / (S_y - S_{pl})$$

(c) For $S_y < S_{al} \leq S_u$

$$(13) f_{apk} = f_{yk} + Z_{2k}(S_{al} - S_y)$$

where

$$(14) Z_{2k} = (f_{uk} - f_{yk}) / (S_u - S_y)$$

[98]

[98]

A-9542 Example Illustrating the Derivation of Linearized Allowable Bending Stress for SA-672 A50 Material at 600°F (316°C)

The values of S_y and S_u are given:

$$S_y = 20.0 \text{ ksi yield strength at } 600^\circ\text{F (Section II, Part D, Subpart 1, Table Y-1)}$$

$$S_u = 50.0 \text{ ksi ultimate tensile strength at } 600^\circ\text{F (Section II, Part D, Subpart 1, Table U)}$$

The following values of S_{oy} and S_{ou} are found from Fig. A-9541-2:

$$S_{oy} = 11 \text{ ksi}$$

$$S_{ou} = 44 \text{ ksi}$$

Using Eqs. (6) and (8),

$$f_{ul.5} = 50 + 0.5(44) = 72 \text{ ksi}$$

$$f_{yl.5} = 20.0 + 0.5(11) = 25.5 \text{ ksi}$$

or, using Fig. A-9541-3,

$$f_{ul.5} = 72 \text{ ksi}$$

$$f_{yl.5} = 25 \text{ ksi}$$

Using Eqs. (7) and (9), the value of f_{uk} and f_{yk} , for any K , is determined. For example, if $K = 1.9, 1.7, 1.3$, and 1.1 , then

$$f_{ul.9} = 72.0 + 0.4(44.0) = 89.6 \text{ ksi}$$

$$f_{ul.7} = 72.0 + 0.2(44.0) = 80.8 \text{ ksi}$$

$$f_{ul.3} = 72.0 + (-0.2)(44.0) = 63.2 \text{ ksi}$$

$$f_{ul.1} = 72.0 + (-0.4)(44.0) = 54.4 \text{ ksi}$$

$$f_{yl.9} = 25.5 + 0.4(11.0) = 29.8 \text{ ksi}$$

$$f_{yl.7} = 25.5 + 0.2(11.0) = 27.6 \text{ ksi}$$

$$f_{yl.3} = 25.5 + (-0.2)(11.0) = 23.2 \text{ ksi}$$

$$f_{yI.I} = 25.5 + (-0.4)(11.0) = 21.0 \text{ ksi}$$

From Fig. A-9541-4, $S_{pl} = 13.0$ ksi. Using the above data, Fig. A-9542-1 may be obtained for $K = 1.9$, 1.5 , and 1.1 .

From F-1323.3, the allowable stress is the lesser of $1.2S_y$ and $0.7S_u$:

$$1.2S_y = 1.2(20) = 24 \text{ ksi}$$

$$0.7S_u = 0.7(50) = 35.0 \text{ ksi}$$

Therefore, $S_{al} = 24.0$ ksi and

$$S_y = 20 \text{ ksi}$$

$$S_u = 50 \text{ ksi}$$

$$\therefore S_y < S_{al} < S_u$$

From Eq. (14), with $K = 1.5$,

$$Z = (72 - 25.5)/(50 - 20) = 1.55$$

From Eq. (13),

$$f_{qp} = 25.5 + 1.55(24 - 20)$$

$$= 31.7 \text{ ksi}$$

Alternatively, from Fig. A-9542-1, $f_{qp} = 31.5$ ksi.

ARTICLE B-1000 INTRODUCTION AND SCOPE

B-1100 INTRODUCTION

B-1110 OBJECTIVE

(a) The objective of this Appendix is to provide a guide for the preparation of the Design Specification required by this Section. The writer of the Design Specification is not restricted as to what can be included therein except that, as a minimum, the information required by this Section must be included. Additional, but not less restrictive, requirements which modify the rules of this Section to make them complete for a specific component or to provide more specific or restrictive requirements should be identified.

(b) It is recognized that in order to prepare a document that provides a complete basis for construction of an item for a nuclear power plant, a number of considerations outside the scope of this Section may need to be addressed. Some of these which are addressed in this Appendix are:

- (1) load combinations;
- (2) operability;
- (3) regulatory requirements.

The additional guidance provided in this Appendix for these considerations is not required by this Section, is not a part of the certification process, and should not be interpreted as extending the duties of the Inspector.

B-1120 FORMAT

B-1120.1 General.

Design Specifications should be as uniform throughout the nuclear industry as is reasonably attainable. The format of this Appendix is presented as a guide to uniformity and is divided into major categories as follows:

- (a) *Generic Requirements* applicable to all components (B-2000);
- (b) *Specific Requirements* applicable to each component (B-3000 through B-10000, inclusive).
- (c) Included in both the Generic and Specific Requirements are those considerations outside the scope of this Section (operability¹ and regulatory² requirements) which have an effect on construction but which are not required by this Section to be a part of the certified Design Specification.

B-1120.2 Nomenclature, Definitions, and Symbols.

Nomenclature, definitions, and symbols should be in agreement with those established in the applicable Article. Should a conflict exist between Articles, the Design Specification should be clear as to what is intended in each case.

B-1200 SCOPE OF CERTIFIED DESIGN SPECIFICATION

The certified Design Specification should contain in sufficient detail the information which this Section requires to be provided. Operability¹ and regulatory² requirements which are beyond the jurisdiction of this Section are not covered by the Code required certification of the Design Specification (NCA-1110).

¹ Applicable operability requirements are contained in the Subarticles designated 200 in this Appendix, such as B-2200, B-3200, etc.

² Applicable regulatory requirements are contained in the Subarticles designated 300 in this Appendix, such as B-2300, B-3300, etc.

ARTICLE B-2000 GENERIC REQUIREMENTS

B-2100 CERTIFIED DESIGN SPECIFICATION REQUIREMENTS

The information in this Article addresses those portions of the certified Design Specification which are generic in nature and therefore applicable to the construction of all Section III items.

B-2110 GENERAL

B-2110.1 Contents of the Certified Design Specification

(a) NCA-3252 provides the minimum requirements for the contents of the certified Design Specification.

(b) With respect to NCA-3252(a), it is important to recognize that the boundary defines an interface between two items that are dependent on each other for the transmittal of loads. In order to properly design the item on either side of the boundary, the effect of the attached item is required. The effect may be furnished directly by supplying the forces and moments that are transmitted across the boundary or, alternatively, by providing sufficient information to enable the designer to determine the interaction across the boundary. This Section provides rules to accomplish this in NCA-3254.

(c) Any Code Cases applicable to the construction of an item should be included in the Design Specification.

B-2110.2 Certification.

NCA-3255 provides the requirements for certification of the Design Specification. The required certification is not applicable to supplementary, regulatory, or operability requirements which are outside of the scope of this Section.

B-2110.3 Permanent Records.

NCA-4134.17 provides the requirements for the continued maintenance and retention location for permanent records.

B-2110.4 Handling, Storage, and Shipping.

The Design Specification should include any special measures to control handling, storage, and shipping of the component (NCA-4134.13).

B-2110.5 Identification of Enforcement Authorities.

The Design Specification should include identification of enforcement authorities at locations of component installation with whom Data Reports must be filed.

B-2110.6 Filing.

NCA-3256 provides the requirements for filing of the Design Specification.

B-2110.7 Review of Design Report.

NCA-3260 provides the requirements for review of the Design Report.

B-2111 Classification

B-2111.1 Responsibility.

NCA-2110 provides the requirements for classification of equipment.

B-2111.2 Multiple Code Class Components.

NCA-2133 provides the requirements for multiple Code Class components.

B-2111.3 Optional Use of Code Classes.

NCA-2134 provides the requirements for optional use of Code Classes.

B-2111.4 Special Requirements.

NCA-2160 provides the requirements for contractual arrangements that are beyond the scope of this Section.

B-2112 Design Basis and Service Limits

B-2112.1 Plant and System Service Conditions.

The definition of plant and system service conditions, and the determination of their significance to the design and operability of components and supports of a nuclear power system, may be derived from systems safety criteria documents for specific types of nuclear power systems and may be found in the requirements of regulatory authorities having jurisdiction at the site [NCA-2141(b)].

Page 257

B-2112.2 Design Loadings.

The Design Specification shall include the Design Pressure [NCA-2142.1(a)], the Design Temperature [NCA-2142.1(b)], and the Design Mechanical Loads [NCA-2142.1(c)].

B-2112.3 Establishment of Component and Component Support Design and Service Limits

(a) For Class 1, MC, and CS components, and for Class 2 and 3 piping and its supports, Design and Service Loads should be specified and appropriate Service Limits designated [NCA-2142(a)].

(b) For Class 2 and 3 components and supports, other than piping and its supports, two options are available as follows:

(1) Design and Service Loads may be specified and appropriate Service Limits designated.

(2) Service Loadings are not required to be identified when the Design Pressure, Design Temperature, and Design Mechanical Loads result in stresses that are at least as high, relative to allowable values, as any which may occur for any Service Loading [NCA-2142(a)].

B-2112.4 Test Loadings.

NCA-2142.3 provides the rules for consideration of Test Loadings.

B-2113 N Certificate Holder's Responsibilities

B-2113.1 Manufacturers of Small Pumps and Valves and of Component Standard Supports.

Manufacturers of small pumps and valves (4 in. NPS and smaller) and component standard supports (including snubbers) who elect to provide their own Design Specification are responsible for compliance with the requirements of NCA-3256(b).

B-2113.2 Compliance With N Certificate Holder's Responsibilities.

When the completed Code item involves work by more than one organization, the Design Specification shall be provided to the organization having overall responsibility.

B-2120 DESIGN

B-2121 Loadings

The Owner or Owner's designee shall identify the loadings and designate the appropriate Design and Service Limits for each component or support. The loadings that should be taken into account in designing a component include, but are not limited to, the following:

- (a) internal and external pressure, including static head;
- (b) weight of the component and normal contents under service and test conditions;
- (c) superimposed loads, such as other components, operating equipment, insulation, or corrosion resistant or erosion resistant linings and piping;
- (d) vibrations and earthquake loads;
- (e) reactions of supporting lugs, rings, saddles, or other types of supports;
- (f) temperature effects;
- (g) restrained thermal expansion;
- (h) anchor and support movement effects;
- (i) environmental loads, such as wind and snow;
- (j) dynamic effects of fluid flow.

B-2122 Design Loads

B-2122.1 Design Pressure.

NCA-2142.1(a) and NB/NCND/NE-3112.1 provide the required definitions for Design Pressure.

B-2122.2 Design Temperature.

NB/NCND/NE/NF/NG-3112 and NCA-2142.1(b) provide the requirements for Design Temperature. The Design Temperature shall be used in computations involving the Design Pressure and coincidental Design Mechanical Loads. The actual metal temperature at the point under consideration shall be used in all computations where the use of the actual service pressure is required. Where a component is heated by tracing, induction coils, jacketing, or by internal heat generation, the effect of such heating shall be incorporated in the establishment of the Design Temperature.

B-2122.3 Design Mechanical Loads

(a) The specified Design Mechanical Loads should be selected so that when combined with the effects of Design Pressure, they represent the most severe coincident loadings for which the Level A Service Limits on primary stress are applicable.

(b) The determination of *most severe coincident loadings* may result in specification of pairs of Design Conditions since the one most severe combination may not be readily predicted. The specification may specify the maximum Design Mechanical Load for any situation which, when taken with the Design Pressure, would result in the worst combination of Design Conditions even though they may not be coincident.

(c) The Design Mechanical Loads that are considered are somewhat dependent on the component, its location, its attachment to other components, and for a Class 2 or 3 component, whether Service Loadings are to be specified (refer to B-2112.3 and NCA-2142).

Page 258

B-2123 Service Loads

In order to properly specify Service Limits for the various types of loadings, the Owner or Owner's designee should recognize the basis for the establishment of those Limits. These are given in NCA-2142.2.

B-2123.1 Service Limits A and B

(a) For Class 1, MC, and CS components and for Class 2 vessels designed to NC-3200, Service Limits A and B are provided in order to evaluate the effect of system operating loads on the fatigue life of the component. For a fatigue

analysis the loads applicable to the component being considered should be described in terms of quantities that the designer may use [NB-3222.4(e)]. The variation with respect to time of pressure, temperature, flow rate, etc., as well as the number of times these changes occur in the life of the component, is needed. In this regard, a service cycle is defined in NB-3213.15 as: "... the initiation and establishment of new conditions followed by a return to the conditions which prevailed at the beginning of the cycle." Thus, as an example, the conditions associated with plant startup do not constitute a service cycle. Startup and shutdown together constitute a service cycle, and if there are n_1 startups in the Design Specification, there should be the same number of shutdowns.

(b) Figure B-2123-1 is an illustration of the time - dependent load information which the designer needs. (Note that it provides only the startup portion of a service cycle.)

(c) For Class 2 and 3 piping and its supports, it is not necessary to define each service cycle in detail. What is needed is the maximum range of conditions and the number of occurrences to which the piping will be subjected. For example, the minimum temperature conditions could be 40°F (4°C) while the maximum is 456°F (236°C). If all other service cycles did not impose a temperature condition less than the minimum or greater than the maximum, they would not have to be specified. An exception to this would be ranges of temperatures that occurred more than 7000 times which resulted in significant stresses.

(d) For all other Class 2 and 3 components and component supports, it is not necessary to define each service cycle in detail since no fatigue analysis is required. It is important for the designer to know the maximum loading condition on the component for these Service Limits.

B-2123.2 Service Limit C.

Service Limit C is provided in order to evaluate the effect of plant operating loads on the structural integrity of a component for situations which are not anticipated to occur for a sufficient number of times to affect fatigue life and for which large deformations in areas of structural discontinuities are not objectionable. Since the occurrence of stress associated with this Limit may result in removal of the component from service for inspection or repair, the Owner should review the selection of this Limit for compatibility with established system safety criteria.

B-2123.3 Service Limit D.

Service Limit D is provided in order to evaluate the effect of plant operating loads on the structural integrity of a component for situations in which gross general deformations, loss of dimensional stability, and damage requiring repair, excluding loss of pressure retaining function, are not objectionable. Since the occurrence of stress associated with this Limit may require removal of the component from service, the Owner should review the selection of this Limit for compatibility with established system safety criteria.

B-2124 Test Loads

Loads due to tests beyond those allowed by this Section should be classified in the appropriate Service Limit in accordance with NCA-2142.3(b) [NCA-2142.4(d)-2].

B-2125 Load Combinations

In order to provide a complete definition of service loads, the combination of specific events must be considered. Since these combinations are a function of specific systems which make up a part of a specific type nuclear facility, this Section does not directly address this other than to provide different Stress Limits for various loadings. Specific guidance is provided in the approved Safety Analysis Report (SAR) for the plant.

B-2126 Deformation Limits

The Code does not provide specific deformation limits other than those that would be associated with a given allowable stress. If control of deformation is a requirement, the deformation limits should be provided.

FIG. B-2123-1 TIME-DEPENDENT LOAD INFORMATION

FIG. B-2123-1 TIME-DEPENDENT LOAD INFORMATION

B-2130 MATERIALS

B-2131 General Requirements

The Design Specification should provide information relative to materials as listed in (a) through (g) below:

- (a) any hydrostatic testing or service temperature limits;
- (b) any reductions to design stress intensity values, allowable stress, or fatigue curves necessitated by environmental conditions;
- (c) any restrictions on cladding materials;

- (d) materials which are acceptable from the standpoints of environment and location;
- (e) any restrictions on heat treating;
- (f) any requirements with respect to cleanliness;
- (g) impact test requirements (B-2132);
- (h) any corrosion or erosion allowances;
- (i) postweld heat treatment times applied to the material or item after it is completed must be specified (NB/NC/ND/NE/NF/NG-4622).

B-2132 Impact Tests

For those cases where impact testing is optional, the Design Specification should state whether or not impact testing of the pressure retaining material of the component or the support material is required. The test temperature should be specified and the tests become part of the appropriate Subsection.

B-2140 FABRICATION

The Design Specification should specify any unusual restrictions on fabrication processes or techniques that would be deleterious to the suitability of the component in the expected service environment.

B-2150 TESTING

B-2151 Pneumatic Test

The Design Specification should identify if a pneumatic test should be used in lieu of hydrostatic testing for those components and appurtenances required to be pressure tested in accordance with the rules of this Section (NB-6111, NB-6112, NE-6112).

B-2152 Restriction on Testing

Any restrictions on the use of the test fluid should be provided (NB-6112, NE-6112). When selecting a fluid for the test, it should be determined that the test fluid does not have deleterious effects and that the test fluid may be safely used at the pressure and temperature specified for the test.

B-2153 Bellows Type Expansion Joints

Any requirements that supplement hydrostatic or pneumatic testing of bellows type expansion joints should be included.

B-2154 Leak Tightness

Leak tightness requirements for areas, such as permanent seals, seats, and gasketed joints for pressure retaining components or appurtenances, should be included (NB-6215).

B-2155 Additional Testing

If testing in addition to pressure testing is required, the loads due to such testing should be classified in accordance with NCA-2142.2(b) (NCA-2145).

B-2160 OVERPRESSURE PROTECTION

B-2161 General Requirements

B-2161.1 Scope.

For steady state or transient conditions of pressure and coincident temperature that are in excess of design or service

loadings and their combinations and associated limits specified in the Design Specifications, system overpressure protection is required for vessels, piping, pumps, and valves in service and subjected to the consequences of the application of these conditions (refer to NB/NC/ND-7110).

B-2161.2 Integrated Overpressure Protection.

It should be recognized that the overpressure protection of pressure retaining components in a system require consideration of the pressure transients which may be imposed on the systems during all service loadings and testing conditions described in the component Design Specifications [refer to NB-7120(a)].

B-2162 Design Secondary Pressure

The design secondary pressure shall be specified in the Design Specification [refer to NB-7111(d) and NC/ND-7112].

Page 261

B-2163 Maximum Anticipated Pressure and Temperature

The Design Specification should identify the maximum anticipated pressure and coincident temperature among any systems components under the operating conditions of the system as a consequence of any transients occurring either within the system or in associated systems which may affect the system for which overpressure protection is intended (refer to NB/NC/ND-7300). Service conditions such as at startup and shutdown may require protection against nonductile failure [NB-3211(d)] at pressures lower than the component design pressure.

B-2164 Pressure Relief Valve Operating Requirements

B-2164.1 Blowdown Requirements.

The Design Specification may specify blowdown requirements with a greater tolerance than the values stated in NB/NC/ND-7500.

B-2164.2 Popping Point Tolerance.

The Design Specification may specify a popping point tolerance greater than the value stated in NB/NC/ND-7500.

B-2165 Pressure Relief Valve Operating Characteristics (Refer to ANSI N278.1)

As applicable, the following pressure relief valve operating characteristics should be specified in the Design Specification when overpressure protection is dependent upon these factors:

- (a) set pressure;
- (b) set pressure range;
- (c) set pressure tolerance;
- (d) discharge capacity with due allowance for the effect of the back pressure on the capacity;
- (e) accumulation;
- (f) blowdown;
- (g) static and dynamic back pressure, minimum and maximum;
- (h) response time (maximum time delay between attainment of set pressure or reception of the energizing signal by the solenoid and valve lift).

B-2166 Rupture Disk Devices

Rupture disk device burst pressure tolerance and manufacturing design range should be specified in the Design Specification.

B-2200 OPERABILITY

B-2210 INTRODUCTION

Operability requirements are outside the scope of this Section (NCA-2142); however, the Owner or Owner's designee is required to identify any such requirements in the Design Specifications (NCA-3252).

B-2220 ACTIVE PUMPS OR VALVES

The Design Specification should indicate if the specified pump or valve must perform a mechanical motion during the course of accomplishing a system safety function during or following the specified plant event. Such a pump or valve is designated as an active component.

B-2300 REGULATORY REQUIREMENTS

In the process of preparing a Design Specification, it is important to refer to and rely on the requirements contained in SAR documents since they provide the basis for complying with existing regulatory requirements. Conflicts between a Design Specification and the SAR could lead to construction of items not in compliance with the license requirements. A reference list of regulatory documents is provided in B-11000 which may be used in determining the applicable requirements to be included in a Design Specification.

Page 262

ARTICLE B-3000 SPECIFIC VESSEL REQUIREMENTS

B-3100 CERTIFIED DESIGN SPECIFICATION REQUIREMENTS

The Design Specification for vessels should include requirements indicated in B-2000, Generic Requirements.

Page 263

ARTICLE B-4000 SPECIFIC PUMP REQUIREMENTS

B-4100 CERTIFIED DESIGN SPECIFICATION REQUIREMENTS

In addition to the Design Specification requirements indicated in B-2000, Generic Requirements, the Design Specification for pumps should include the other requirements of B-4110 and B-4120.

B-4110 GENERAL REQUIREMENTS

Covered by B-2110.

B-4120 DESIGN

B-4121 Loads From Connected Piping

The forces and moments produced by the connected piping on each pump inlet and outlet should be included (NB/NC/ND-3415).

B-4122 Earthquake Loadings

NB/NC/ND-3417 provide the requirements for consideration of earthquake loading.

B-4200 OPERABILITY REQUIREMENTS FOR PUMPS

B-4210 GENERAL REQUIREMENTS

B-4211 Applicability

The inclusion of functional operability requirements in the Design Specifications should be based on the functional requirements of the pump being specified. These requirements should be specified only if the pumps are considered to be active pumps.

B-4220 DESIGN

The Design Specification should include all applicable and pertinent information considered important to the functional operability of the pump.

B-4230 QUALIFICATION

B-4231 Methods

The method of pump qualification, if any, for functional operability should be defined in the Design Specification. Qualification by analysis, test, or combinations thereof should be specified. Available codes or standards which cover these areas should be referred to and used to the maximum extent possible.

B-4232 Analysis

Acceptable methods of analysis should be identified. The following areas, as a minimum, should be addressed:

- (a) required analysis;
- (b) load combinations, including deadweight, thermal loads, nozzle loads, seismic loads, etc.;
- (c) allowable stresses for the various loading conditions.

B-4233 Testing

Acceptable methods of testing should be identified. The following areas, as a minimum, should be addressed:

- (a) required tests and test sequences;
- (b) imposed loads and pump function during tests;
- (c) acceptance criteria.

Page 264

B-4240 FUNCTIONAL OPERABILITY PRODUCTION TESTS

Any special functional operability tests to be conducted on production pumps should be specified in the Design Specification.

B-4250 DOCUMENTATION

Documentation requirements for functional qualification or production tests should be specified.

B-4300 REGULATORY REQUIREMENTS

Regulatory requirements are covered in B-2300 and a reference list is given in B-11000.

Page 265

ARTICLE B-5000 SPECIFIC VALVE REQUIREMENTS

B-5100 CERTIFIED DESIGN SPECIFICATION REQUIREMENTS

In addition to the Design Specification requirements indicated in B-2000, Generic Requirements, the Design Specification for valves should include the other requirements of B-5110 and B-5120.

B-5110 GENERAL REQUIREMENTS

Covered by B-2110.

B-5120 DESIGN

B-5121 Class 1 Valves

B-5121.1 Pipe Reactions for Valves Designed to Alternative Design Rules.

NB-3512.2 provides the requirements concerning pipe reactions.

B-5121.2 Earthquake Loadings.

NB-3524 provides the requirements concerning earthquake loadings.

B-5121.3 Level C Service Limits.

NB-3526 provides the requirements concerning valve function during loading for which Level C Service Limits are specified.

B-5121.4 Pipe Reaction Stress.

NB-3526.2 provides the requirements concerning pipe reaction stress computation for Level C Service Limits.

B-5121.5 Level D Service Limits.

NB-3527 provides the requirements concerning valve function during loadings for which Level D Service Limits are specified.

B-5121.6 Hydrostatic Tests.

NB-3531.2(c) provides the requirements concerning alternative test pressures, seat leakages, and test durations.

B-5121.7 Body Contours at Weld Ends.

NB-3544.8 provides the requirements concerning alternative body contours at weld ends of valves.

B-5121.8 Bypass Piping.

The Design Specification shall state which organization is responsible for the bypass piping design, if the responsible organization is not the piping system designer [NB-3546.3(b)].

B-5122 Class 2 Valves

B-5122.1 Alternative Rules.

The Design Specification shall specify whether the alternative rules of NC-3513 are permitted to be used.

B-5122.2 Hydrostatic Tests.

NC-3514 provides the requirements concerning alternative test pressures, seat leakages, and test durations.

B-5123 Class 3 Valves

B-5123.1 Alternative Rules.

The Design Specification shall specify whether the alternative rules of ND-3513 are permitted to be used.

B-5123.2 Hydrostatic Tests.

ND-3514 provides the requirements concerning alternative test pressures, seat leakages, and test durations.

B-5200 OPERABILITY REQUIREMENTS FOR VALVES

B-5210 INTRODUCTION

Operability requirements are outside the scope of this Section (NCA-2142); however, the Owner or Owner's designee is required to identify any valve operability requirements in the Design Specification [NB-3526(b) and NB-3527].

B-5220 DESIGN

The Design Specification should include all applicable and pertinent information required. A document pertaining to this information is ANSI N278.1. Additional

Page 266

information not covered in ANSI N278.1, but considered important to the functional operability of the valve should also be included. NB-3524, NC-3520, and ND-3520 provide guidance for analysis of valves with extended masses.

B-5230 QUALIFICATION

B-5231 Methods

The method of valve qualification, if any, for functional operability should be defined in the Design Specification. Qualification by analysis, test, or combinations thereof should be specified. Available Codes or Standards which cover these areas should be referenced and used to the maximum extent possible.

B-5232 Analysis

Acceptable methods of analysis should be identified. The following areas, as a minimum, should be addressed:

- (a) required analysis;
- (b) load combinations, including seismic, end loads, mechanical loads, etc.;
- (c) allowable stresses for the various loading conditions.

B-5233 Testing

Acceptable methods of testing shall be identified. The following areas, as a minimum, should be addressed:

- (a) required tests and test sequence
- (b) imposed loads and valve function during tests
- (c) acceptance criteria Y

B-5240 FUNCTIONAL OPERABILITY PRODUCTION TESTS

Any special functional operability tests to be conducted on production valves shall be specified in the Design Specification.

B-5250 DOCUMENTATION

Documentation requirements for functional qualification or production tests or both should be specified in the Design Specification.

B-5300 REGULATORY REQUIREMENTS

Regulatory requirements are covered in B-2300 and a reference list is given in B-11000.

ARTICLE B-6000 SPECIFIC PIPING REQUIREMENTS

B-6100 CERTIFIED DESIGN SPECIFICATION REQUIREMENTS

In addition to the Design Specification requirements indicated in B-2000, Generic Requirements, the Design Specification for piping should include the other requirements of B-6110 and B-6120.

B-6110 GENERAL REQUIREMENTS

Covered by B-2110.

B-6120 DESIGN

B-6121 Seismic

For piping, the loadings, movements, anchor motions, and number of cycles due to seismic events should be given. The associated Service Loadings which occur with, or as a result of, the specified seismic events should be stated.

B-6122 Other Dynamic Loads

Dynamic loadings, such as those resulting from sudden valve or pump operation, should be given. As a minimum, the information needed to determine this loading should be given (such as pressures, temperatures, flow rates, valve operating times).

B-6123 Peak Pressure

Peak pressure for Level B, C, and D Service Limits must be restricted to certain values in accordance with NC/ND-3611.2(c)(2), (3), and (4). In categorizing Service Loadings into appropriate Service Limits, the Design Specification should include the peak pressure.

ARTICLE B-7000 SPECIFIC CONTAINMENT REQUIREMENTS

B-7100 CERTIFIED DESIGN SPECIFICATION REQUIREMENTS

In addition to the Design Specification requirements indicated in B-2000, Generic Requirements, the Design Specification for containment should include the other requirements of B-7110 and B-7120.

B-7110 GENERAL REQUIREMENTS

Covered by B-2110.

B-7120 DESIGN

B-7121 Design Pressure

NE-3112.1 provides the requirements concerning specification of Design Pressure.

B-7122 Design Temperature

NE-3112.2 provides the requirements concerning specification of Design Temperature.

B-7123 Design Mechanical Loads

NE-3112.3 provides the requirements concerning specification of Design Mechanical Loads.

B-7124 Service Conditions

NE-3113 provides the requirements concerning specification of Level A, B, C, and D Service Conditions which satisfy the Generic Requirements for Service Limits in NCA-2142.

Page 269

ARTICLE B-8000 SPECIFIC COMPONENT SUPPORT REQUIREMENTS

B-8100 CERTIFIED DESIGN SPECIFICATION REQUIREMENTS

In addition to the Design Specification requirements indicated in B-2000, Generic Requirements, the Design Specification for component and piping supports should include the other requirements of B-8110, B-8120, and B-8130.

B-8110 GENERAL REQUIREMENTS

In addition to the general requirements of B-2110, the information required by NF-1111 for intervening elements in the component support load path should be included in the Design Specification for the supported component.

B-8120 DESIGN

B-8121 Standard Supports

NF-3134 provides the requirements for standard supports.

B-8130 MATERIALS

Requirements for items, such as gaskets, seals, springs, compression spring endplates, bearings, retaining rings, washers, wear shoes, hydraulic fluids, etc., should be stated in the Design Specification. Such items should be made of materials that are not injuriously affected by the fluid, temperature, or irradiation conditions to which the item will be subjected (NF-2121).

B-8300 REGULATORY REQUIREMENTS

Regulatory requirements are covered in B-2300 and a reference list is given in B-11000.

Page 270

ARTICLE B-9000 SPECIFIC CORE SUPPORT STRUCTURES REQUIREMENTS

B-9100 CERTIFIED DESIGN SPECIFICATION REQUIREMENTS

In addition to the Design Specification requirements indicated in B-2000, Generic Requirements, the Design Specification for core support structures should include the other requirements of B-9110, B-9120, B-9130, and B-9140.

B-9110 GENERAL REQUIREMENTS

(a) All information and requirements contained in the specifications which are beyond the jurisdiction of Subsection NG should be so identified.

(b) The Design Specifications should stipulate any specific additional core support structure requirements which the Owner intends to be incorporated in the specific structures covered by the Design Specifications or any additional requirements intended to be more specific or more restrictive than the minimum requirements of this Section.

(c) Where additional terms, definitions, or expressions are required, they should be clearly defined and explained and adequately referenced.

(d) Identification of the core support structure is required as determined by their function and operating requirements (Structures whose purpose is only to limit the motion of the core following the postulated occurrence of a failure in the structure normally supporting the core are not considered core support structures. They are normally designed to meet deformation limits for this postulated condition and are not intended to meet the stress limits of NG-3200.) (NG-1121).

(e) Delineation of those internal structures which are required to be analyzed in order to ensure the structural integrity of the mating core support structures (NG-1122).

(f) The boundaries of the core support structures and their relationship to the support and restraint of the core shall be clearly defined through the use of dimensions, descriptions, or drawings (NG-1120).

B-9120 DESIGN

B-9121 Loading Conditions

The following should be specified:

- (a) pressure differences due to coolant flow;
- (b) weight of the core support structure;
- (c) superimposed loads, such as those due to other structures, the reactor core, steam separating equipment, flow distributors and baffles, thermal shields, and safety equipment;
- (d) earthquake loads or other loads which result from motion of the reactor vessel;
- (e) reactions from the support or restraints, or both;
- (f) loads due to temperature effects, such as thermal gradients and differential expansion;
- (g) loads resulting from the impingement or flow of reactor coolant or other contained or surrounding fluids;
- (h) transient pressure difference loads, such as those which would result from rupture of the main coolant pipe;
- (i) vibratory loads;
- (j) reaction loads from control rods;
- (k) handling loads experienced in preparation for or during refueling or inservice inspection.

B-9122 Loading Combinations

The loadings to be simultaneously considered and the applicable Service Limits should be specified (NG-3112).

Page 271

B-9123 Deformation Limits

In addition to Service Limits given in Subsection NG, static and dynamic deformation limits should be specified to ensure the performance of all safety related functions of the core support structure. These limits are to be those that cause loss of function and are not intended to include a margin of safety (NG-3220).

B-9124 Reinforcement for Openings

The Design Specification should stipulate if the rules for reinforcing applicable to Class 1 vessels may be used for core support structures (NB-3132).

B-9130 MATERIALS

The Design Specifications should provide any special requirements for materials and testing specifically applicable to the core support structures. The Owner is responsible for selecting materials suitable for the conditions stated at the Design Specification with specific attention being given to the effects of service conditions upon the properties of the materials (NB-2160). The requirements for impact testing shall be specified [NG-2311(a)].

B-9140 FABRICATION

The extent or removal of additional material by mechanical means when P-No. 8 material is prepared by thermal cutting

ARTICLE B-10000 SPECIFIC PARTS AND MISCELLANEOUS ITEMS REQUIREMENTS

B-10100 CERTIFIED DESIGN SPECIFICATION REQUIREMENTS

In addition to the Design Specification requirements indicated in B-2000, Generic Requirements, the Design Specification for parts and miscellaneous items should include the other requirements of B-10110.

B-10110 GENERAL REQUIREMENTS

The following general requirements should be considered when preparing a Design Specification for parts and miscellaneous items.

B-10111 Parts

The Design Specification for components or component supports should apply to the parts of such components or component supports (NCA-2131).

B-10112 Appurtenances

NCA-1260 provides the requirements for appurtenances.

B-10113 Control Rod Drive Housings

NCA-1271 provides the requirements for control rod drive housings.

B-10114 Heater Elements

NCA-1272 provides the requirements for heater elements.

B-10115 Fluid Conditioner Devices

NCA-1273 provides the requirements for fluid conditioner devices.

ARTICLE B-11000 REFERENCE LIST OF REGULATORY REQUIREMENTS

B-11100 INTRODUCTION

This list is intended as a guide only and it should be recognized that new regulatory requirements may exist that are not listed or that some of those listed may be revised or voided.

B-11200 TITLE 10 OF CODE OF FEDERAL REGULATIONS

Title 10 of the Code of Federal Regulations (10 CFR) includes requirements on the use, construction, and operation of production and utilization facilities, such as nuclear power plants. Of particular importance to the construction of nuclear components and safety related structures are Part 50 of the regulations, "Licensing of Production and Utilization Facilities," and Part 100 of the regulations, "Reactor Site Criteria." The following portions of 10 CFR Parts 50 and 100 highlight requirements that should be considered in the preparation of Design Specifications.

(a) 10 CFR Part 50.55a constitutes one of the most important of the regulations relative to the Design Specifications. Among other requirements, it designates the Codes and Standards and their Editions and Addenda that must be used for pressure retaining components and within the reactor coolant pressure boundary.

(b) 10 CFR 50.59 - Changes, Tests, and Experiments;

- (c) 10 CFR 50.109 - Backfitting;
- (d) Appendix A to 10 CFR Part 50 - General Design Criteria;
- (e) Appendix B to 10 CFR Part 50 - Quality Assurance Criteria;
- (f) Appendix G to 10 CFR Part 50 - Fracture Toughness Requirements;
- (g) Appendix H to 10 CFR Part 50 - Reactor Vessel Material Surveillance Program;
- (h) Appendix J to 10 CFR Part 50 - Containment Leak Testing;
- (i) Appendix M to 10 CFR Part 50 - Standardization of Design;
- (j) Appendix N to 10 CFR Part 50 - Standardization of Nuclear Power Plant Design;
- (k) Appendix O to 10 CFR Part 50 - Standardization of Designs;
- (l) Appendix A to 10 CFR Part 100 - Seismic and Geological Siting.

APPENDIX C CERTIFICATE HOLDER'S DESIGN REPORT

Page 277

C-1100 INTRODUCTION

C-1110 OBJECTIVE

The objective of this Appendix is to provide a guide for use by Certificate Holders in the preparation of Design Reports required by NCA-3551.1. Desirably, such Design Reports should be uniform as to format for all of the nuclear industry. Such uniformity is helpful in making for easier review by the Owner (NCA-3260), Inspectors, regulatory agencies, or independent groups. For NF supports designed by load rating (NF-3280), the preparation of a load capacity data sheet in accordance with NCA-3551.2 fulfills the requirements for preparation of a Design Report. The contents of this Appendix constitute only suggestions and are nonmandatory.

C-1120 BASIS

In order to meet the requirements of NCA-3551, the Design Report should be based upon analysis or testing adequate to

demonstrate the validity of the structural design to sustain and meet in every respect the requirements and provisions of the relevant certified Design Specifications and the requirements of this Section; the Report should include, as a minimum, the results, conclusions, and other considerations which show that the structural design meets these requirements.

C-1130 FORMAT

C-1131 General Requirements

Since a major purpose of the Design Report is to facilitate an independent review of its content, it is important that it be simple to follow and free from ambiguity. Nomenclature, definitions, and symbols used should be in agreement with those established in Subsection NB for Class 1 components, in Subsection NE for Class MC vessels, in Subsection NF for supports, in Subsection NG for Class CS core support structures, and in Subsection NC for vessels designed in accordance with NC-3200. Where additional terms, definitions, or expressions are required, they should be clearly defined and explained and adequately referenced. It is not the intention to limit the choice of analytical methods or computational techniques used for obtaining the values and results required for the Design Report.

C-1132 Presentation of Analysis

The analysis in the Design Report should be in three sections: Thermal Analysis, Structural Analysis, and Fatigue Evaluation. The desiderata listed in (a) through (j) below should be adhered to:

- (a) pages and figures in each section of the Report should be consecutively numbered;
- (b) reference data taken from other parts of the calculations should have the proper page number and section of the Report listed;
- (c) a general description of the method of analysis should be given;
- (d) all reference sources should be listed;
- (e) all computer programs should be properly identified and described;
- (f) stresses should be tabulated for each area of investigation;
- (g) areas which have the most severe stress condition for design conditions or for any specified transient should be listed in the Report, along with the stress values in these areas;
- (h) results should be summarized and a general summary of all stresses should be made in each section of the Report;
- (i) drawings and sketches necessary for an understanding of the analysis should be part of the Report;
- (j) the Report should include copies of sufficient computer printouts to justify the governing stress values used in the Design Report and enable independent review. Copies of any manual calculations prepared which establish the final design should also be included.

Page 280

C-1140 BASIC INFORMATION

It should be noted that the references in this Appendix to basic information which is to be obtained from the certified Design Specifications (NCA-3250) are predicated on the requirement of NCA-3252 that such information be provided.

C-1150 DISTRIBUTION OF COPIES OF DESIGN REPORT

Copies of the completed certified Design Report (NCA-3355) should be made available for the Owner's review, certification, and distribution as required by NCA-3556, NCA-3260, and NCA-3270. The Certificate Holder shall also make a copy available to the Inspector (NCA-3557).

C-1200 THERMAL ANALYSIS

C-1210 DESCRIPTIONS OF OPERATING CYCLES

Data for the various transients and operating cycles should be obtained from the certified Design Specifications. Typical cycles which should be considered are referenced in Appendix B.

C-1220 STEADY STATE CONDITION

The steady state condition to provide a thermal equilibrium condition for normal operating transients should be obtained from the certified Design Specifications.

C-1230 GEOMETRY FROM TEMPERATURE DISTRIBUTION POINT OF VIEW

The geometrical structure of the component should be divided into suitable areas for thermal analysis. Sketches of the thermal model should be included in the Report. The areas listed in (a) through (m) below are typical of those that should be investigated:

- (a) nozzle junctions in the component wall;
- (b) stud bolts;
- (c) cylinder junction with cylinder flange;
- (d) point of support attachment;
- (e) cylinder junction with head;
- (f) junction of component wall and internal baffles, tubesheets, and attachments;
- (g) tube-to-tubesheet junction for heat exchangers;
- (h) heater penetrations to component junction for pressurizer;
- (i) junction area between component supports and building structure;
- (j) external attachments;
- (k) changes in thickness within a component (such as a reducer, branch connection, component support, etc.) or across a welded joint (such as a socket weld, butt weld of different thickness, etc.);
- (l) instrument penetrations to component junction (such as thermowells, flow devices, etc.);
- (m) core barrel and core support plate.

C-1240 GEOMETRIES FROM STRESS INVESTIGATION POINT OF VIEW

The final breakdown of the geometries, which will correspond to the method of stress calculation, should be indicated in the calculations. Typical areas listed in C-1230 which are applicable to the component under consideration should be included.

C-1250 TEMPERATURE-DEPENDENT DATA FOR EACH THERMAL GEOMETRY AND TRANSIENT

The Certificate Holder should specify values for all parameters, such as coefficients for water and air, which are required for thermal calculations. References to sources should be given for all such data used.

C-1260 TEMPERATURE DISTRIBUTION FOR EACH GEOMETRY

The temperature profile of the applicable areas listed under C-1230 should be calculated and the temperature values attached to the calculations. The temperature distributions should be based on two or three dimensional heat transfer calculations. For calculating through wall (radial) temperature distributions to obtain values of ΔT_1 and ΔT_2 (NB-3650), one-dimensional heat transfer calculations are acceptable.

C-1270 THERMAL GRADIENTS

Individual transients should be investigated separately for each area. The longitudinal, radial, and circumferential gradients should be plotted separately. The temperature gradients used in the stress calculations should be plotted.

Page 281

C-1300 STRUCTURAL ANALYSIS

C-1310 IMPORTANT THERMAL AND MECHANICAL LOADING ON COMPONENT STRUCTURE

C-1311 Mechanical Loading

The mechanical loads used in the Design Report to calculate primary stresses should be obtained directly from the Design Specification (such as Design Pressure and Temperature) or from information contained in the Design Specification (such as seismic spectra, valve opening and/or closing times, etc.).

C-1312 Thermal and Mechanical Loading

Specific reference should be made to the thermal transients and resulting gradients which are to be used for the Design Report. The internal pressure and external loads to be used should be in accordance with the time and thermal condition analyzed. Values for external nozzle loads should include sign convention of the loadings and be referenced specifically to the geometries.

C-1320 METHODS OF CALCULATIONS

The Certificate Holder should submit a short description of the calculation methods used in connection with the stress analysis. All computer programs used in making calculations should be verified by comparing the program with the results of an appropriate analytical or experimental solution. The basic theories on which the calculations are based and the assumptions should also be included.

C-1330 PRINCIPAL STRESSES FOR EACH GEOMETRY

In calculating stress components, the requirements of NB-3200, NC-3200, NE-3200, NF-3220, NF-3230, or NG-3200 should be followed. The following are typical of stress components that should be considered:

(a) Mechanical stresses generated by:

- (1) pressure load
- (2) deadweight load
- (3) piping load
- (4) externally applied load
- (5) seismic loads
- (6) dynamic loads

(b) Thermal stresses generated by:

- (1) radial gradient
 - (a) thermal stress
 - (b) thermal discontinuity stress
- (2) longitudinal gradient
 - (a) thermal stress
 - (b)

C-1340 ALLOWABLE LIMITS

Each individual stress component and combination of the stress components should satisfy the requirements of NB-3220, NC-3220, NE-3220, NF-3220, NF-3230, or NG-3220.

C-1400 FATIGUE EVALUATION

C-1410 SCOPE OF FATIGUE EVALUATION

Fatigue evaluation when required should include the considerations and investigations described in this Subarticle.

C-1420 LOCATIONS OF STRESS CONCENTRATIONS

Stress concentration should be investigated at any geometrical changes in the structure, such as difference in wall thickness, joints and corners, and junctions of dissimilar metals. A list of the locations subject to fatigue evaluation should be included in the Report. For piping, K indices are given for standard piping components in NB-3600 which represent elastic stress concentration factors.

C-1430 FATIGUE STRENGTH REDUCTION FACTORS AS FUNCTION OF LOCATIONS AND TYPES OF STRESS

Fatigue strength reduction factors should be numerically listed for the stresses where they are to be applied. The references and methods of finding the fatigue strength reduction factors should be included in the Report.

Page 282

C-1440 PROPER STRESS CONCENTRATION OR FATIGUE STRENGTH REDUCTION FACTOR APPLICATION TO STRESSES

The numerical value of the individual stress components should be listed with and without the stress concentration or fatigue strength reduction factor applied. Factors should be applied to each individual stress component and not applied to the total stress at a point or to the stress intensity.

C-1450 COMBINED STRESSES AND ALLOWABLE NUMBER OF CYCLES

Where the rules do not specifically control this, as they do in NB-3500 and NB-3600, methods of combining stresses, determining principal stresses, determining alternating stress intensity, and determining cumulative damage effects and allowable number of cycles should be shown in the Report. These results should be reconciled with the required values.

SEC III D1 NMA APP D

APPENDIX D NONMANDATORY PREHEAT PROCEDURES

Page 283

ARTICLE D-1000 NONMANDATORY PREHEAT PROCEDURES

D-1100 INTRODUCTION

D-1110 SCOPE

The preheat temperatures given herein are a general guide for the materials listed in P-Numbers of Section IX. Specific rules for preheating are not given since the need for preheat and the minimum preheat temperatures vary and are dependent on a number of factors, such as chemical analysis, degree of restraint, physical properties, and thickness. Preheat

requirements for different materials of the same P-Number may be more or less restrictive depending upon the specific circumstances associated with making a particular weld. The welding procedure specification for the material being welded shall specify the minimum preheating requirements under the welding procedure qualification requirements of Section IX (NB-4611).

D-1120 TEMPERATURE MAINTENANCE

(a) Difficulty may be experienced with certain materials if the temperature is allowed to fall below the preheat temperature between passes. It may be desirable to maintain the preheat temperature or to heat the joint to the postweld heat treatment temperature before allowing it to cool to ambient temperature.

(b) The preheat temperature may be checked by suitable methods, such as temperature-indicating crayons or thermocouple pyrometers, to ensure that the required preheat temperature is maintained during the welding operation. The Certificate Holder should be cautious in the use of temperature-indicating crayons and pellets because some metals may be severely attacked by the chemicals in crayons or pellets at elevated temperatures.

D-1200 FERROUS MATERIALS

D-1210 PREHEAT TEMPERATURES

Suggested minimum preheat temperatures are given in the following subparagraphs.

D-1210.1 P-No. 1, Group 1.

200°F (93°C) is suggested for material that has a maximum carbon content of 0.30% or less and a thickness in excess of $1\frac{1}{2}$ in. (38 mm). 250°F (121°C) is suggested for material that has both a maximum carbon content in excess of 0.30% and a thickness in excess of 1 in. (25 mm). This does not apply to fillet welds $\frac{1}{2}$ in. (13 mm) and less in size that are used to attach insulation clips and other parts not carrying loadings due to internal pressure. 50°F (10°C) is suggested for all other materials in this group.

D-1210.2 P-No. 1, Group 2.

200°F (93°C) is suggested for material that has a maximum carbon content of 0.30% or less and a thickness in excess of 1 in. (25 mm). 250°F (121°C) is suggested for material that has a maximum carbon content in excess of 0.30% and a thickness in excess of 1 in. (25 mm).

D-1210.3 P-No. 1, Group 3 and P-No. 3 and P-No. 11A.

250°F (121°C) is suggested for material that has either a specified maximum tensile strength in excess of 70.0 ksi (480 MPa) or a thickness at the joint in excess of $\frac{5}{8}$ in. (16 mm). 50°F (10°C) is suggested for all other materials in this group.

D-1210.4 P-No. 4.

300°F (149°C) is suggested for material that has either a specified minimum tensile strength in excess of 60.0 ksi (410 MPa) or a thickness at the joint in excess of $\frac{1}{2}$ in. (13 mm). 50°F (10°C) is suggested for all other materials in this group.

D-1210.5 P-No. 5.

400°F (204°C) is suggested for material that has either a specified minimum tensile strength in excess of 60.0 ksi (410 MPa) or has both a specified minimum chromium content above 6.0% and a thickness at the joint in excess of $\frac{1}{2}$ in. (13 mm).

Page 286

300°F (149°C) is suggested for all other materials in this group.

D-1210.6 P-No. 6.

400°F (204°C) is suggested for all materials.

D-1210.7 P-No. 7 and P-No. 8.

None is suggested.

D-1210.8 P-No. 9.

300°F (149°C) is suggested for all materials.

D-1210.9 P-No. 10

(a) 175°F (79°C) is suggested for P-No.10A.

(b) 250°F (121°C) is suggested for P-No.10B.

(c) Preheat and interpass temperatures should be controlled for various thicknesses to avoid detrimental effects on the mechanical properties of heat treated material.

(d) 300°F (149°C) is suggested for P-No. 10D and P-No. 10E with interpass at 300 - 450°F (149 - 232°C).

APPENDIX E MINIMUM BOLT CROSS-SECTIONAL AREA

Page 287

E-1100 INTRODUCTION

[98]

E-1110 SCOPE

This Article implements NB-3230 by providing specific methods for the determination of the minimum bolt cross-sectional area. Stresses in the bolts during service must also satisfy the requirements of NB-3232.2 and NB-3232.3. Evaluation of service bolt stresses requires analysis in addition to that described by this Article, generally involving the performance of a discontinuity analysis in accordance with the principles described in A-6000.

[98]

E-1120 NOMENCLATURE

The nomenclature defined below is used in the equations of this Article.

A_b	= actual total cross-sectional area of bolts at root of thread or section of least diameter under stress, sq in.
A_m	= total design cross-sectional area of bolts, taken as the greater of A_{m1} and A_{m2} sq in.
A_{m1}	= total cross-sectional area of bolts at root of thread or section of least diameter under stress, required for the Design Conditions, sq in. $= W_{m1}/S_b$
A_{m2}	= total cross-sectional area of bolts at root of thread or section of least diameter under stress, required for gasket seating, sq in.

	<i>m2 a</i>
b	= effective gasket or joint contact surface seating width, in. (E-1210, footnote ¹)
b_o	= basic gasket seating width, in. (Table E-1210-2)
G	= diameter at location of gasket load reaction. G is defined as follows (Table E-1210-2): when $b_o \leq \frac{1}{4}$ in., G is the mean diameter of gasket contact face, in.; when $b_o > \frac{1}{4}$ in., G is the outside diameter, in., of gasket contact face less $2b$.
H	= total hydrostatic end force, lb = $0.785G^2P$
m	= gasket factor obtained from Table E-1210-1 [footnote ¹ to E-1210(a)(1)]
N	= width, in., used to determine the basic gasket seating width, b_o , based upon the contact width of the gasket (Table E-1210-2)
P	= Design Pressure, psi
S_a	= allowable bolt stress at atmospheric temperature, psi (Section II, Part D, Subpart 1, Table 4)
S_b	= allowable bolt stress at Design Temperature, psi (Section II, Part D, Subpart 1, Table 4)
T	= thickness, in., used to determine the basic gasket seating width, b_o (Table E-1210-2)
W_{m1}	= minimum required bolt load for the Design Pressure, lb (E-1210)
W_{m2}	= minimum required bolt load for gasket seating, lb (E-1210)
w	= width, in., used to determine the basic gasket seating width b_o based upon the contact width between the flange facing and the gasket (Table E-1210-2)
y	= minimum design seating stress, psi

E-1200 DESIGN CROSS-SECTIONAL AREA

[98]

E-1210 BOLT LOADS

(a) *Design Bolt Loads.* The flange bolt loads used in calculating the design cross-sectional area of bolts shall be determined as stipulated in (1) and (2) below.

(1) The design bolt load for the Design Pressure W_{m1} shall be sufficient to resist the hydrostatic end force H , exerted by the Design Pressure on the area bounded by the diameter of gasket reaction, and, in addition, to maintain on the gasket or joint contact surface a compression load H_p , which experience has shown to be sufficient to ensure a tight joint. This compression load is expressed as a multiple m of the internal pressure. Its value is a function of the gasket

Page 290

material and construction.¹ The design bolt load for the Design Pressure W_{m1} is determined in accordance with Eq. (1).

$$W_{m1} = H + H_p$$

$$= 0.785G^2P + (2b \times 3.14GmP) \quad (1)$$

(1)

Tables E-1210-1 and E-1210-2 give a list of many commonly used gasket materials and contact facings with suggested values of m , b , and y that have proved satisfactory in actual service. These values are suggested only and are not mandatory. Values that are too low may result in leakage at the joint, without affecting the safety of the design. The primary proof that the values are adequate is the hydrostatic test.

(2) Before a tight joint can be obtained it is necessary to seat the gasket or joint contact surface properly by applying a minimum initial load, under atmospheric temperature conditions without the presence of internal pressure, which is a function of the gasket material and the effective gasket area to be seated. The minimum initial bolt load W_{m2} required for this purpose, shall be determined in accordance with Eq. (2).

$$(2) W_{m2} = 3.14bGy$$

The need for providing sufficient bolt load to seat the gasket or joint contact surfaces in accordance with Eq. (2) will prevail on many low pressure designs and with facings and materials that require a high seating load, and where the bolt load, computed by Eq. (1) for the Design Pressure, is insufficient to seat the joint. Accordingly, it is necessary to furnish bolting and to pretighten the bolts sufficiently to satisfy both of these requirements, each one being individually investigated. When Eq. (2) governs, flange proportions will be a function of the bolting instead of internal pressure.

(b) *Minimum Required and Actual Bolt Areas A_m and A_b* The minimum cross-sectional area of bolts A_m required for both the Design Pressure and gasket seating is the greater of the values for A_{m1} and A_{m2} , where $A_{m1} = W_{m1}/S_b$ and $A_{m2} = W_{m2}/S_a$. A selection of bolts to be used shall be made such that the actual total cross-sectional area of bolts A_b will not be less than A_m (NB-3230).

(c) Bolt Loads for Flanges Using Gaskets of the Self-Energizing Type

(1) The design bolt load for the Design Pressure W_{m1} shall be sufficient to resist the hydrostatic end force H , exerted by the maximum allowable working pressure on the area bounded by the outside diameter of the gasket. H_p is to be considered as 0 for all self-energizing gaskets, except certain seal configurations that generate axial gasket loads which shall be considered.

$$(2) W_{m2} = 0.$$

Self-energizing gaskets are considered to be those that require only an inconsequential amount of bolt force to produce an initial seal. The bolting, however, may have to be sufficiently pretightened to prevent extrusion of the gasket, to prevent cyclic fatigue of the bolts, or to resist any external loads or moments that may be imposed on the joint.

NOTES:

- (1) This Table gives a list of many commonly used gasket materials and contact facings with suggested design values of m and y that have generally proved satisfactory in actual service when using effective gasket seating width b given in Table E-1210-2. The design values and other details given in this Table are suggested only and are not mandatory.
- (2) The surface of a gasket having a lap should not be against the nubbin.

TABLE E-1210-1 (CONT'D) GASKET MATERIALS AND CONTACT FACINGS¹

APPENDIX F RULES FOR EVALUATION OF SERVICE LOADINGS WITH LEVEL D SERVICE LIMITS

Page 295

ARTICLE F-1000 RULES FOR EVALUATION OF SERVICE LOADINGS WITH LEVEL D SERVICE LIMITS

F-1100 INTRODUCTION

F-1110 SCOPE

This Appendix provides rules and service limits which may be used by Owners and N-Type Certificate Holders for evaluating components and supports subjected to loads for which Level D Service Limits are specified by the Design Specification (NCA-3250).

F-1200 INTENT OF LEVEL D SERVICE LIMITS

(a) The Level D Service Limits and design rules contained in F-1300 are provided for limiting the consequences of the specified event. They are intended (NCA-2142) to assure that violation of the pressure retaining boundary will not occur, but are not intended to assure operability of components either during or following the specified event.

(b) The limits and rules specified for core support structures are intended to assure maintenance of structural integrity but not to prevent leakage.

(c) The limits and rules of this Appendix need not be applied to that portion of a component or support in which a failure has been postulated.

F-1300 LEVEL D SERVICE LIMITS AND DESIGN RULES

F-1310 GENERAL

(a) These limits and design rules are provided to limit the consequences of loads for which Level D Service Limits are specified in the Design Specification.

(b) The contents of F-1320 provide general procedures which are applicable to all components and supports. Specific procedures, which may be used as alternatives to the procedures of F-1320, are provided as follows:

F-1400 Vessels

F-1410 Pumps

F-1420 Valves

F-1430 Piping

F-1440 Core Support Structures

(c) Only limits on primary stresses are prescribed. Unless specifically required by this Appendix, self-relieving stresses resulting from loads for which Level D Service Limits are specified need not be considered.

(d) When compressive stresses are present the stability of the component or component support shall be considered.

(e) Potential for unstable crack growth shall also be considered.

F-1320 DESIGN BY ANALYSIS

F-1321 Terms Related to Analysis

Terms used in this paragraph relating to analysis are defined in the following subparagraphs. Additional definitions are given in NB-3213.

F-1321.1 System Analysis.

System analysis is performed to determine loads on components and supports. A system is an assemblage of components, supports, and other interconnected structures. The system analysis is generally dynamic due to the nature of the loads.

F-1321.2 Component and Support Analysis.

Component analysis is the calculation of stresses and displacements in a component or support to determine compliance with the service limits listed herein. Loads applied in the component analysis and support analysis shall include those determined in a system analysis plus additional loads as applicable.

Page 298

F-1321.3 Elastic Analysis.

Elastic analysis is based on the assumption of a linear relationship between stress and strain. Consideration of gaps between parts of the structure may cause the relationship between loads and deformations to be nonlinear.

F-1321.4 Inelastic Analysis.

Inelastic analysis is a class of methods which computes structural behavior considering nonlinearities in the relationship between stresses and strains. Inelastic analysis as applied in this Appendix shall not be considered to include the time dependent effects of creep.

(a) *Limit Analysis.* Limit analysis is that method which computes the maximum load or combination of loads a structure made of ideally plastic (nonstrain-hardening) material can carry. Limit analysis for components is described in NB-3213.21 and NB-3213.22 and for linear supports in NF-3340.

(b) *Plastic Analysis.* Plastic analysis is defined in NB-3213.24.

F-1321.5 Interaction Method.

Interaction method (formerly Stress Ratio Method) is a method used to evaluate the adequacy of structures under combined loads. Procedures for the method are described in A-9000.

F-1321.6 Collapse.

Collapse of a structure occurs upon formation of an unstable mechanism of plastic hinges under a given combination of loads. The collapse load is defined as follows:

(a) *limit analysis collapse load* is defined in NB-3213.28;

(b) *test collapse load* is defined as that load determined by test according to the criteria given in II-1430;

(c) *plastic analysis collapse load* is defined as that load determined by plastic analysis according to the criteria given in II-1430.

F-1321.7 Plastic Instability Load.

Plastic instability load is defined in NB-3213.26.

F-1321.8 Experimental Stress Analysis.

Experimental stress analysis is a method for evaluation of structural behavior, based on direct measurement of response of test specimens, where the configuration of the model and the applied loads are representative of the component or support under consideration. Response parameters measured are selected to provide data appropriate to

the acceptance criteria applied. Experimental methods are provided for in Appendix II.

F-1321.9 Primary Stress Intensities.

The definitions of general primary membrane stress intensity, designated as P_m ; local primary membrane stress intensity, designated as P_L ; and primary bending stress intensity, designated as P_b , are provided in NB-3221.

F-1322 Methods and Requirements for Analysis

The following requirements shall be satisfied in the evaluation of components or supports under the loads or load combinations for which Level D Service Limits are specified.

F-1322.1 Analysis Combinations

(a) System analysis may be performed by elastic analysis methods as defined in F-1321.3 or by plastic analysis methods as defined in F-1321.4(b). If elastic system analysis is used, the components and supports shall be designed to meet the acceptance criteria in F-1330. If plastic system analysis is used, the components and supports may be designed based on the acceptance criteria in F-1340.

(b) If elastic system analysis is used, the components and supports may be designed based alternatively on the acceptance criteria of F-1340 provided a reevaluation of the system analysis is performed to determine that it has not been significantly invalidated due to load and stress redistribution and changes in geometry. Some of the conditions under which this analysis combination may be acceptable are:

- (1) the plastic deformation is highly localized; or
- (2) the changes in geometry are not significant.

This combination may also be considered valid if bounding solutions are established which conservatively account for redistribution of loads and stresses due to plasticity.

(c) If all loads on a component or support are determined independently from system behavior (e.g., specified pressures), then the component or support may be designed based on acceptance criteria in either F-1330 or F-1340.

(d) The Design Specification for the components and supports shall indicate what type of system analysis (if any) has been used to derive the specified loads.

F-1322.2 Dynamic Effects.

Postulated events for which Level D Service Limits are specified are generally dynamic in nature. The determination of loads for components and supports shall account for dynamic amplification of structural response, both in the component and in the system.

F-1322.3 Material Behavior

(a) The mechanical and physical properties shall be taken from Section II, Part D, Subpart 2 at the actual temperature of the material. The allowable stresses shall

Page 299

be based on material properties given in Section II, Part D, Subpart 2 at temperature. If S_u values at temperature are not tabulated in Section II, Part D, Subpart 2, Table U,¹ the value used shall be included and justified in the Design Report.

(b) The stress and strain allowables given in this Appendix are based on an engineering stress-strain curve. If another type of stress-strain curve (e.g., true stress-strain or Kirchoff stress-strain) is used, the results from the analysis or the allowables given in this Appendix shall be appropriately transformed.

(c) When performing plastic analysis, the stress-strain curve used shall be included and justified in the Design Report. It is permissible to adjust the stress-strain curve to include strain rate effects resulting from dynamic behavior. However, the allowables shall be selected in accordance with (a) above.

(d) The yield criteria and associated flow rule used in the inelastic analysis may be either those associated with the maximum shear stress theory (Tresca) or the strain energy distortion theory (Von Mises).

F-1322.4 Geometric Nonlinearities.

Geometric nonlinearities may be produced by relatively large deformations and/or rotations and by gaps between parts of the structure. Analyses performed for derivation of loads and for evaluation of acceptability of components and supports shall consider geometric nonlinearities if appropriate.

F-1322.5 Strain and/or Deformation Limits.

In addition to the limits given in this Appendix, the strain or deformation limits (if any) provided in the Design Specification shall be satisfied.

F-1330 ACCEPTANCE CRITERIA USING ELASTIC SYSTEM ANALYSIS

The acceptance criteria in this Section shall be applied when elastic system analysis is used to determine loads on components and supports. These criteria are subject to the restrictions on methods of evaluation stated in F-1322.

1 In addition to Section II, Part D, Subpart 2, Table U, S_u values are also available in Code Cases covering new or additional materials for components and their supports.

F-1331 Criteria for Components

F-1331.1 Elastic Analysis

(a) The general primary membrane stress intensity P_m shall not exceed the lesser of $2.4S_m$ and $0.7S_u$ for materials included in Section II, Part D, Subpart 1, Tables 2A and 2B for austenitic and high alloy steels, or $0.7S_u$ for ferritic materials included in Table 2A.

(b) The local primary membrane stress intensity P_L shall not exceed 150% of the limit for general primary membrane stress intensity P_m .

(c) The primary membrane (general or local) plus primary bending stress intensity $P_L + P_b$ shall be limited in accordance with one of the following provisions:

(1) stress intensity $P_L + P_b$ shall not exceed 150% of the limit for general primary membrane stress intensity P_m ;

(2) static or equivalent static loads shall not exceed 90% of the limit analysis collapse load using a yield stress which is the lesser of $2.3S_m$ and $0.7S_u$ or 100% of the plastic analysis collapse load or test collapse load (F-1321.6).

(d) The average primary shear stress across a section loaded in pure shear shall not exceed $0.42S_u$.

F-1331.2 Interaction Method.

As an alternative to the requirements of F-1331.1 above, acceptability of individual members of components may be demonstrated using the interaction method. Procedures for interaction method analysis are given in A-9000. The allowable stress S_{al} shall not exceed the lesser of $2.4S_m$ and $0.7S_u$.

F-1331.3 Bearing Stresses.

Except for pinned and bolted joints, bearing stresses need not be evaluated for loads for which Level D Service Limits are specified.

F-1331.4 Stress Limits for Bolts.

Bolts shall be evaluated in accordance with the rules of F-1335.

F-1331.5 Requirements for Compressive Loads.

Components subjected to compressive loads shall be evaluated against buckling limits. Maximum compressive load (or stress) shall be limited to a value established by (a), (b), or (c) below.

(a) Two-thirds of the value of buckling load (or stress) determined by one of the methods given below:

(1) comprehensive analysis which considers effects such as geometric imperfections, deformations due to existing loading conditions, nonlinearities, large deformations, residual stresses, and inertial forces; or

(2) tests of physical models under conditions of restraint and loading the same as those to which the configuration is expected to be subjected;

(b) a value equal to 150% of the limit established by the rules of NB-3133, except that the pressure is permitted to be 250% of the given value when the ovality is limited to 1% or less; or

(c) a value determined in accordance with the procedures contained in a Code Case for metal containment

Page 300

shell buckling design methods using a factor of safety of 1.34.

F-1332 Criteria for Plate and Shell Type Supports

The criteria presented in this paragraph pertain to primary stresses only. Stresses resulting from constraint of free end displacement and anchor point motion (NF-3121.12 and NF-3121.13) shall be considered primary stresses in the evaluation. Neither peak stresses nor stresses resulting from thermal expansion within the support need be evaluated.

F-1332.1 Primary Membrane Stress Intensity.

The general primary membrane stress intensity P_m is limited to the greater of $1.2S_y$ and $1.5S_m$ but may not exceed $0.7S_u$.

F-1332.2 Primary Membrane Plus Bending Stress Intensity.

The general primary membrane plus primary bending stress intensity, $P_m + P_b$, shall be limited in accordance with one of the following provisions:

(a) 150% of the limit for general primary stress intensity P_m ; or

(b) static or equivalent static loads shall not exceed 90% of the limit analysis collapse load (F-1321.6) using a yield strength which is the lesser of $1.2S_y$ and $0.7S_u$, or 100% of the plastic analysis collapse load or test collapse load (F-1321.6).

F-1332.3 Bearing Stress.

Except for pinned and bolted joints, bearing stresses need not be evaluated for loads for which Level D Service Limits are specified.

F-1332.4 Pure Shear.

The average primary shear across a section loaded in pure shear shall not exceed $0.42S_u$.

F-1332.5 Requirements for Compressive Stresses.

Plate and shell type supports subject to compressive stresses shall be evaluated in accordance with the rules of F-1331.5(a).

F-1332.6 Stress Limits for Bolts.

Bolts shall be evaluated in accordance with the rules of F-1335.

F-1332.7 Load Rating.

As an alternative to the requirements of F-1332.1 through F-1332.6 above, plate and shell type supports may be qualified to Service Level D Limits using the procedure for load rating (NF-3282). The load rating for Level D Service Loadings shall be determined by the following equation:

$$\text{load rating} = \text{TL} \times 0.7 \frac{S_u}{S_u^*}$$

where

TL

= support test load equal to or less than the load under which the support fails to perform its specified support function, lb

S_u

= tensile strength of the support material at temperature, ksi

S_u^*

= tensile strength of the support material at test temperature, ksi

but

$$\frac{S_u}{S_u^*} \leq 1$$

F-1333 Criteria for Standard Supports

Criteria in F-1332 or F-1334 shall be applied according to whether standard supports are plate and shell or linear type

supports.

F-1334 Criteria for Linear Type Supports

The criteria presented in this paragraph pertain to primary stresses only. Stresses resulting from constraint of free end displacement and anchor point motion (NF-3121.12 or NF-3121.13) shall be considered primary stresses in the evaluation.

Neither peak stresses nor stresses resulting from thermal expansion within the support need be evaluated.

Unless otherwise specified, the allowable stresses presented (NF-3320) for Level A Service Condition may be increased using the following factors: the smaller of 2 or $1.167S_u/S_y$, if $S_u > 1.2S_y$, or 1.4 if $S_u \leq 1.2S_y$, where S_y is the yield strength, ksi, and S_u is the ultimate tensile strength, ksi, both at temperature. In addition, members must be checked for local and general instability.

F-1334.1 Stresses in Tension.

The tensile stress on the net section, except at pin holes and in the through-plate thickness direction, shall not exceed the lesser of $1.2S_y$ and $0.7S_u$.

F-1334.2 Stresses in Shear.

The shear stress on the gross section shall not exceed the lesser of $0.72S_y$ and $0.42S_u$. Gross section shall be determined in accordance with NB-3322.1(b).

F-1334.3 Axial Compression.

Maximum load in axially loaded compression members shall be limited in accordance with either (a) or (b) below.

Page 301

(a) Two-thirds of the buckling load, as determined by one of the following methods:

(1) comprehensive stability analysis which considers effects such as large deformations, deformations due to existing loading conditions, material nonlinearities, local buckling, out-of-straightness and other tolerances, load eccentricity, end conditions, residual stresses and inertia loads (for dynamic loading); or

(2) testing of a full-scale prototype under conditions of support and loading the same as those to which the actual compression member is expected to be subjected;

(b) the maximum allowable load for ferritic steels shall be determined in accordance with the following provided that the initial out-of-straightness does not exceed 1/1000 of the unsupported length. Effects of deformations due to existing loads shall also be considered.

(1) Except as noted in (2) below, the following rules shall be applied:

For $0 \leq \lambda \leq 1$

$$\frac{P}{P_y} = \frac{1 - \lambda^2 / 4}{1.11 + 0.50\lambda + 0.17\lambda^2 - 0.28\lambda^3}$$

For $1 \leq \lambda \leq \sqrt{2}$

$$\frac{P}{P_y} = \frac{2}{3} (1 - \lambda^2 / 4)$$

For $\lambda > \sqrt{2}$

$$\frac{P}{P_y} = \frac{2}{3\lambda^2}$$

where

P

= maximum allowable load, lb

P_y

= $S_y A_g$, lb

A_g

= area of gross section, in.²

$$\lambda = \left(\frac{KL}{r} \right) \frac{1}{\pi} \sqrt{\frac{S_y}{E}}$$

E

= modulus of elasticity, psi

K

= effective length factor

L

= unbraced length, in.

r

= radius of gyration, in.

(2) For nonstress-relieved heavy structural shapes (web or flange thickness greater than 1 in.) or for nonstress-relieved built-up members using universal mill plate, the following rules shall be applied:

For $0 < \lambda < 1$

$$\frac{P}{P_y} = \frac{1 - \lambda^2 / 4}{1.11 + 0.75\lambda + 0.83\lambda^2 - 0.81\lambda^3}$$

For $1 < \lambda < \sqrt{2}$

$$\frac{P}{P_y} = \frac{1 - \lambda^2 / 4}{1.88}$$

For $\lambda > \sqrt{2}$

$$\frac{P}{P_y} = \frac{1}{1.88\lambda^2}$$

F-1334.4 Combined Axial Tension and Bending

(a) For members subject to both axial tension and bending stresses, the following equation shall be satisfied:

$$\frac{f_a}{F_a} + \frac{f_{bx}}{F_{bx}} + \frac{f_{by}}{F_{by}} \leq 1$$

where

$$F_a = \text{smaller of } 1.2S_y \text{ or } 0.7S_u \text{ ksi}$$

(b) For members qualifying as compact sections under criteria of NF-3322.1(d)(1), the maximum bending stress shall be given by:

$$F_b = fS_y$$

where

$$f = \text{plastic shape factor for the cross section}$$

(c) If members do not meet the compact section requirements, they shall be designed using one of two methods below to determine F_b for use in the equation above.

(1) Allowable values for F_b given in NF-3322.1(d)(2) may be increased by a factor of 1.11 (to maintain a nominal factor of safety of 1.5 against instability).

(2) Rigorous analysis of member stability may be used to determine critical bending stress. A factor of safety of 1.5 shall be used in determining allowable design bending stress.

F-1334.5 Combined Axial Compression and Bending.

Members subject to combined axial compression and bending shall satisfy Eqs. (20), (21), and (22) of NF-3322.1 (e)(1) with allowable stresses defined as follows.

(a) $F_a = P/A_g$ where P shall be determined in accordance with F-1334.3.

(b) The value of F'_e shall be taken as:

$$F'_e = \frac{\pi^2 E}{1.30(Kl_b / r_b)^2}$$

with terms as defined in NF-3313.1.

(c) F_b shall be determined using F-1334.4(b) or (c) as appropriate.

F-1334.6 Collapse Load Analysis.

As an alternative to the requirements in F-1334.4 above, acceptability of linear type supports may be established using one of the methods given below:

- (a) using lower bound limit analysis given in NF-3340, static or equivalent static loads shall not exceed 90% of the limit analysis collapse load using a yield stress which is the greater of $1.2S_y$ and $1.5S_m$, but not larger than $0.7S_u$;
- (b) 100% of the plastic analysis collapse load; or
- (c) 100% of the test collapse load (F-1321.6).

F-1334.7 Interaction Method.

As an alternative to the requirements of F-1334.1 through F-1334.5 above, acceptability for individual structural members of linear type supports may be demonstrated using the interaction method. Procedures for interaction method analysis are given in A-9000. The allowable stress S_{at} shall not exceed the greater of $1.2S_y$ and $1.5S_m$, but not larger than $0.7S_u$.

F-1334.8 Load Rating.

As an alternative to the requirements of F-1334.1 through F-1334.5 above, linear type supports may be qualified to Service Level D Limits using load rating criteria given in F-1332.7.

F-1334.9 Stress Limits for Bolts.

Bolts shall be evaluated in accordance with the rules of F-1335.

F-1334.10 Bearing Stresses.

Except for pinned and bolted joints, bearing stresses need not be evaluated for loads for which Level D Service Limits are specified.

F-1335 Requirements for Bolted Joints

(a) The requirements provided in this Section shall be applied to components and supports. Threaded structural fasteners used in core support structures shall be evaluated using the rules of F-1440.

(b) Allowable stresses for bolts are given in the paragraphs below. These allowable stresses are only applicable if the bolt stresses are calculated using elastic methods.

F-1335.1 Allowable Tensile Stress.

The average tensile stress computed on the basis of the available tensile stress area shall not exceed the smaller of 0.7 S_u and S_y . When high strength bolts or threaded parts having an ultimate tensile strength greater than 100 ksi at operating temperature are used in component applications, the maximum value of the stress at the periphery of the bolt cross section resulting from direct tension plus bending and excluding stress concentrations shall not exceed S_u . The bolt load shall be the sum of the external load and any bolt tension resulting from prying action produced by deformation of the connected parts.

F-1335.2 Allowable Shear Stress

(a) For bearing type joints, the average bolt shear stress expressed in terms of available shear stress area shall not exceed the smaller of $0.42S_u$ and $0.6S_y$.

(b) Friction type joints shall be evaluated using the rules of NF-3324.6(a)(3)(b).

F-1335.3 Combined Tensile and Shear Stress

(a) Bolts subjected to combined shear and tension in bearing type joints shall be so proportioned that the shear and the tensile stresses satisfy the following equation:

$$\frac{f_t^2}{F_{tb}^2} + \frac{f_v^2}{F_{vb}^2} \leq 1$$

where

f_t

= computed tensile stress, ksi

f_v

= computed shear stress, ksi

F_{tb}

= allowable tensile stress at temperature per F-1335.1, ksi

F_{vb} = allowable shear stress at temperature per F-1335.2(a), ksi

(b) In friction type joints, the joint clamping force will be reduced by any direct tension load on the joint. Therefore, the bolt clamping force used to calculate the allowable shear load in NF-3324.6(a)(3)(b) shall be reduced by an equivalent amount.

F-1335.4 Minimum Edge Distance in Line of Load.

In both bearing and friction type joints, the minimum distance from the center of the end bolt to that edge of the connected part toward which the load is directed shall satisfy (a) and (b) below:

$$(a) L/d \geq [0.5 + 1.2 (f_p/S_u)]$$

$$(b) f_p/S_u \leq 2.1$$

where

L = distance from center of bolt hole to edge of connected part, in.

d = nominal diameter of bolt, in.

f_p = nominal bearing stress, ksi
= P/dt

P = bearing load transmitted by the fastener, lb

t = thickness of the connected part, in.

Page 303

S_u = tensile strength of the connected parts at temperature, ksi

F-1336 Requirements for Pinned Joints

Except for bearing, pinned joints shall be evaluated in accordance with the acceptance criteria of F-1331. The allowable bearing stress shall be $2.1S_u$.

F-1340 ACCEPTANCE CRITERIA USING PLASTIC SYSTEM ANALYSIS

The acceptance criteria in this section may be applied provided the system analysis considers effects of material nonlinear behavior. The criteria are subject to the restrictions on methods of evaluation stated in F-1322.

F-1341 Criteria for Components

Acceptability of components may be demonstrated using any one of the following methods:

- (a) elastic analysis
- (b) plastic analysis
- (c) collapse load analysis
- (d) plastic instability analysis
- (e) interaction method

The primary stress limits for these alternative methods are given in F-1341.1 through F-1341.5. The other limits given in F-1341.6 and F-1341.7 shall also be satisfied as applicable.

F-1341.1 Elastic Analysis.

Where the component is evaluated on an elastic basis, the following primary stress limits shall be applied.

(a) The general primary membrane stress intensity P_m shall not exceed the lesser of $2.4S_m$ and $0.7S_u$ for materials included in Section II, Part D, Subpart 1, Tables 2A and 2B, or $0.7S_u$ for materials included in Section II, Part D, Subpart 1, Table 2A.

(b) The local primary membrane stress intensity P_L shall not exceed 150% of the limit for general primary membrane stress intensity P_m .

(c) The primary membrane (general or local) plus primary bending stress intensity, $P_L + P_B$ shall not exceed 150% of the limit for general primary membrane stress intensity P_m .

(d) The average primary shear across a section loaded in pure shear shall not exceed $0.42S_u$.

[98]

F-1341.2 Plastic Analysis.

Where the component is evaluated on a plastic basis the following primary stress limits shall be applied.

(a) The general primary membrane stress intensity P_m shall not exceed $0.7S_u$ for ferritic steel materials included in Section II, Part D, Subpart 1, Table 2A and the greater of $0.7S_u$ and $S_y + \frac{1}{3}(S_u - S_y)$ for austenitic steel, high-nickel alloy, and copper-nickel alloy materials included in Section II, Part D, Subpart 1, Table 2A.

(b) The maximum primary stress intensity at any location shall not exceed $0.90S_u$.

(c) The average primary shear across a section loaded in pure shear shall not exceed $0.42S_u$.

[98]

F-1341.3 Collapse Load.

Static or equivalent static loads shall not exceed 90% of the limit analysis collapse load using a yield stress which is the lesser of $2.3S_m$ and $0.7S_u$ or 100% of the plastic analysis collapse load or test collapse load (F-1321.6).

F-1341.4 Plastic Instability Load.

The plastic instability load (F-1321.7) is designated P_I and may be determined by one of the following methods:

(a) plastic analysis (NB-3213.24);

(b) experimental analysis (F-1321.8).

The applied load shall not exceed $0.7P_I$.

F-1341.5 Interaction Method.

Acceptability for individual members of components may be demonstrated using the interaction method. Procedures for interaction method analysis are given in A-9000. The allowable stress S_{al} shall not exceed $0.7S_u$.

F-1341.6 Bearing Stresses.

Except for pinned and bolted joints, bearing stresses need not be evaluated for loads for which Level D Service Limits are specified.

F-1341.7 Stress Limits for Bolts.

Bolts shall be evaluated in accordance with the rules of F-1335.

F-1341.8 Requirements for Compressive Loads.

Components subjected to compressive loads shall be evaluated in accordance with the rules of F-1331.5.

F-1342 Criteria for Plate and Shell Type Supports

(a) The criteria presented in this paragraph pertain to primary stresses only. Stresses resulting from constraint of free end and anchor point motion (NF-3121.12 and NF-3121.13) shall be considered as primary stresses in the evaluation. Neither peak stresses nor stresses resulting from thermal expansion within the support need be evaluated.

(b) The allowable stresses for plate and shell type supports shall be per F-1341, with material properties

Page 304

provided by the applicable table of Appendix I per Table NF-2121(a)-1.

(c) As an alternative to the requirements of (b) above, plate and shell type supports may be qualified to Service Level D Limits using the procedure for load rating (NF-3282). The load rating for Level D Service Loadings shall be determined by the following equation:

$$\text{load rating} = \text{TL} \times 0.7 \frac{S_u}{S_u^*}$$

where

TL

= support test load equal to or less than the load under which the support fails to perform its specified support function, lb

S_u

= tensile strength of the support material at temperature, ksi

S_u^*

= tensile strength of the support material at test temperature, ksi

but

$$\frac{S_u}{S_u^*} \leq 1$$

F-1343 Criteria for Standard Supports

The rules of F-1342 or F-1344 shall be applied according to whether standard supports are plate and shell or linear type supports.

F-1344 Criteria for Linear Type Supports

The criteria presented in this paragraph pertain to primary stresses only. Stresses resulting from constraint of free end displacement and anchor point motion (NF-3121.12 and NF-3121.13) shall be considered primary stresses in the evaluation. Neither peak stresses nor stresses resulting from thermal expansion within the support need be evaluated.

Acceptability of linear type supports may be demonstrated using any one of the following methods:

- (a) elastic analysis
- (b) plastic analysis
- (c) collapse load analysis
- (d) plastic instability analysis
- (e) interaction method

The primary stress limits for these alternative methods are given in F-1344.1 through F-1344.5. The other limits given in F-1344.6 and F-1344.7 shall also be satisfied as applicable.

F-1344.1 Elastic Analysis.

The criteria provided in F-1334 through F-1334.5 shall be applied.

F-1344.2 Plastic Analysis.

The criteria provided in F-1341.2 shall be applied. In addition, members shall be checked for local and general instability following the requirements given in F-1334.3.

F-1344.3 Collapse Load Analysis.

The criteria provided in F-1334.6 shall be applied.

F-1344.4 Plastic Instability Analysis.

The plastic instability load (F-1321.7) is designated P_I and may be determined by one of the following methods:

(a) plastic analysis [F-1321.4(b)];

(b) experimental analysis (F-1321.8).

The applied load shall not exceed $0.7P_I$.

F-1344.5 Interaction Method.

Acceptability for individual structural members of linear type supports may be demonstrated using interaction method analysis. Procedures for interaction method analysis are given in A-9000. The allowable stress S_{al} shall not exceed $0.7S_{ut}$.

F-1344.6 Stress Limits for Bolts.

Bolts shall be evaluated in accordance with the rules of F-1335.

F-1344.7 Bearing Stresses.

Except for pinned and bolted joints, bearing stresses need not be evaluated for loads for which Level D Service Limits are specified.

F-1400 VESSELS

The design rules given in F-1330 and F-1340 shall be used for evaluation of vessels for loads for which Service Level D Limits are specified.

F-1410 PUMPS

The design rules given in F-1330 and F-1340 shall be used for evaluation of pumps for loads for which Service Level D Limits are specified.

F-1420 VALVES

As an alternative to the procedures of F-1300, the criteria of both (a) and (b) below may used.

(a) The maximum internal pressure shall not exceed the lesser of 2.0 times the Design Pressure and the rated pressure at the temperature for which Service Level D Limits are specified.

(b) Calculate the valve crotch (Fig. NB-3545.2-1, Section A-A) stress intensity S_n due to all applicable loads:

Page 305

$$S_n = 0.5Q_p + P_{es}$$

or

$$S_n = 0.5Q_p + nP_{eb}$$

where

Q_p

= as defined in NB-3545.2

P_{es}

= primary stress in crotch region of valve body caused by piping loads for which Level D Service Limits are specified; includes combined axial, bending, and torsion, ksi

n

= 1.3 for ferritic pipe materials in Section II, Part D, Subpart

1, Table 2A

= 1.5 for Austenitic and high alloy pipe materials in Section II, Part D, Subpart 1, Tables 2A and 2B

P_{eb}

= as defined in NB-3545.2(b)

The allowable value of this stress intensity is the lesser of $3.6S_m$ and $1.05S_u$ for materials in Section II, Part D, Subpart 1, Tables 2A and 2B, or $1.05S_u$ for materials in Section II, Part D, Subpart 1, Table 2A.

F-1430 PIPING

For piping, as an alternative to the procedures of F-1331, the criteria of (a) and (b) below may be used.

(a) The internal pressure shall not exceed 200% of the Design Pressure calculated in accordance with Eq. (2) of NB-3641.1.

(b) When applying the procedures of NB-3652, Eq. (9) of NB-3652 shall be satisfied using a stress limit of $3.0S_m$ or $2S_y$, whichever is less.

F-1440 CORE SUPPORT STRUCTURES

The procedures of F-1300 may be used except as stipulated in (a) through (d) below.

(a) The specified dynamic or equivalent static loads shall not exceed 80% of the ultimate collapse load as obtained from test P_r where P_r is defined as the load at which the horizontal tangent to the load deformation curve occurs, or 80% of a load combination used in the test of a prototype or model. In using this method, account shall be taken of the size effect and dimensional tolerances as well as differences which may exist in the ultimate strength or other governing material properties of the actual part and the tested parts to assure that the loads obtained from the test are a conservative representation of the load carrying capability of the actual component under postulated loading conditions for which Level D Service Limits apply.

(b) For core support structures, component inelastic analysis may be combined with elastic system analysis (F-1331). For this analysis, the maximum stress limit shall be $0.67S_u$ for primary membrane stress intensity, and shall be equal to the greater of $0.67S_{ut}$ and $S_y + 1/3 (S_{ut} - S_y)$, but not to exceed $0.9S_u$ for maximum primary stress intensity, where S_{ut} is defined as the value of ultimate stress obtained from the true stress-strain curve. In this case, the elastic system analysis shall be checked, accounting for component plastic deformation.

(c) The stress limits for high strength threaded structural fasteners having ultimate strength greater than 100 ksi at operating temperatures for core support structure applications are as given in (1) through (3) below. S_m is as tabulated in Section II, Part D, Subpart 1, Tables 2A and 2B.

(1) For component elastic analysis, combined with either elastic or inelastic system analysis, P_m shall not exceed $2S_m$ and $P_m + P_b$ shall not exceed $3S_m$.

(2) For component plastic analysis, combined with either elastic or inelastic system analysis, P_m shall not exceed $2S_m$ and maximum primary stress intensity shall not exceed the larger of $0.67S_{ut}$ and $S_y + 1/3 (S_{ut} - S_y)$, but not to exceed $0.9S_u$ where S_{ut} is defined as the value of ultimate stress obtained from the true stress-strain curve.

(3) For component limit analysis, combined with either elastic or inelastic system analysis, P_m shall not exceed $1.33L_L$ and $P_m + P_b$ shall not exceed $1.33L_L$, where the shape factor is less than or equal to 1.5, with S_y equal to $1.5S_m$ where L_L is defined in Fig. NG-3224-1, Note (6).

(d) The stress limits for threaded structural fasteners having ultimate strength less than or equal to 100 ksi at operating temperatures shall be determined in accordance with F-1331 or F-1341, as appropriate.

APPENDIX G PROTECTION AGAINST NONDUCTILE FAILURE

Page 307

ARTICLE G-1000 INTRODUCTION

This Appendix presents a procedure for obtaining the allowable loadings for ferritic pressure retaining materials in components. This procedure is based on the principles of linear elastic fracture mechanics. At each location being investigated a maximum postulated flaw is assumed. At the same location the *mode I stress intensity factor*¹ K_I is produced by each of the specified loadings as calculated and the summation of the K_I values is compared to a reference value K_{IR} which is the highest critical value of K_I that can be ensured for the material and temperature involved. Different procedures are recommended for different components and operating conditions.

¹ The stress intensity factor as used in fracture mechanics has no relation to and must not be confused with the stress intensity used in Articles of this Section. Furthermore, stresses referred to in this Appendix are calculated normal tensile stresses not stress intensities in a defect free stress model at the surface nearest the location of the assumed defect.

Page 310

ARTICLE G-2000 VESSELS

G-2100 GENERAL REQUIREMENTS

[98]

G-2110 REFERENCE CRITICAL STRESS INTENSITY FACTOR

(a) Figure G-2210-1 is a curve showing the relationship that can be conservatively expected between the critical, or reference, stress intensity factor K_{IR} , $\text{ksi}\sqrt{\text{in.}}$, and a temperature which is related to the reference nil ductility temperature RT_{NDT} determined in NB-2331. This curve is based on the lower bound of static, dynamic, and crack arrest critical K_I values measured as a function of temperature on specimens of SA-533 Type B Class 1, and SA-508 Grade 1, SA-508 Grade 2 Class 1, and SA-508 Grade 3 Class 1 steels. No available data points for static, dynamic, or arrest tests fall below the curve. An analytical approximation to the curve is:

$$K_{IR} = 26.78 + 1.223\exp[0.0145(T - RT_{NDT} + 160)]$$

Unless higher K_{IR} values can be justified for the particular material and circumstances being considered, Fig. G-2210-1 may be used for ferritic steels which meet the requirements of NB-2331 and which have a specified minimum yield strength at room temperature of 50.0 ksi or less.

(b) For materials which have specified minimum yield strengths at room temperature greater than 50.0 ksi (345 MPa) but not exceeding 90.0 ksi (620 MPa), Fig. G-2210-1 may be used provided fracture mechanics data (similar to the K_{ID} data referenced in WRCB 175) are obtained on at least three heats of the material on a sufficient number of specimens to cover the temperature range of interest, including the weld metal and heat-affected zone, and provided that the data are equal to or above the curve of Fig. G-2210-1. These data shall be included in the Design Specification. Where these materials of higher yield strengths [specified minimum yield strength greater than 50.0 ksi (345 MPa) but not exceeding 90.0 ksi (620 MPa)] are to be used in conditions where radiation may affect the material properties, the effect of radiation on the K_{IR} curve shall be determined for the material prior to its use in manufacture. This information shall be included in the Design Specification.

[98]

[98]

G-2120 MAXIMUM POSTULATED DEFECT

The postulated defect used in this recommended procedure is a sharp, surface defect normal to the direction of maximum stress. For section thicknesses of 4 in. to 12 in. (102 mm to 305 mm), it has a depth of one-fourth of the section thickness and a length of $1\frac{1}{2}$ times the section thickness. For sections greater than 12 in. (305 mm) thick, the postulated defect for the 12 in. (305 mm) section is used. For sections less than 4 in. (102 mm) thick, the 1 in. (25 mm) deep defect is conservatively postulated. These postulated defects were used in developing the curves of Fig. G-2214-1. Smaller defect

sizes² may be used on an individual case basis if a smaller size of maximum postulated defect can be ensured. Due to the safety factors recommended here, the prevention of nonductile fracture is ensured for some of the most important situations even if the defects were to be about twice as large in linear dimensions as this postulated maximum defect. [98]

G-2200 LEVEL A AND LEVEL B SERVICE LIMITS

G-2210 SHELLS AND HEADS REMOTE FROM DISCONTINUITIES

G-2211 Recommendations

The assumptions of this Subarticle are recommended for shell and head regions during Level A and B Service Limits.

2 WRCB 175 (Welding Research Council Bulletin 175) "PVRC Recommendations on Toughness Requirements for Ferritic Materials" provides procedures in Paragraph 5c(2) for considering maximum postulated defects smaller than those described.

Page 311

FIG. G-2210-1

FIG. G-2210-1

G-2212 Reference Critical Stress Intensity Factor for Material

The K_{IR} values of Fig. G-2210-1 are recommended.

G-2213 Maximum Postulated Defect

The recommended maximum postulated defect is that described in G-2120.

G-2214 Calculated Stress Intensity Factors

G-2214.1 Membrane Tension.

The K_I corresponding to membrane tension for the postulated defect of G-2120 is $K_{Im} = M_m \times$ membrane stress, where M_m is as shown in Fig. G-2214-1.

G-2214.2 Bending Stress.

The K_I corresponding to bending stress for the postulated defect of G-2120 is $K_{Ib} = M_b \times$ maximum bending stress, where M_b is two-thirds of the M_m shown in Fig. G-2214-1.

[98]

G-2214.3 Radial Thermal Gradient.

The K_I produced by a radial thermal gradient across a wall thickness for the postulated defect of G-2120 is $K_{It} = M_t \times$ temperature difference through the wall, °F, where M_t is as shown in Fig. G-2214-2.

(a) The M_t values in Fig. G-2214-2 are applicable only for the conditions given in (1) and (2).

(1) An assumed shape of the temperature gradient is approximately as shown in Fig. G-2214-3.

(2) The temperature change starts from a steady state condition and has a rate, associated with startup and shutdown, less than about 100°F/hr (56°C/hr). The results would be overly conservative if applied to rapid temperature changes.

(b) If the conditions of (a) above are not met, other means must be used for calculating the K_I produced by thermal stress. For example, the moment produced by the radial thermal gradient may be calculated and the equivalent linear stress [NB-3213.13(a)(3)] considered by the provisions of G-2214.2.

[98]

G-2214.4 Stresses Exceeding Material Yield Strength.

WRCB 175 provides procedures in Paragraph 5C(3) for considering elastically calculated stresses which exceed the yield strength of the material. This

Page 312

method may be used in lieu of using Figs. G-2214-1 through G-2214-3, which are not applicable for combined stresses above the material yield strength.

98

FIG. G-2214-1

[98]

FIG. G-2214-1

[98]

G-2215 Allowable Pressure

The equations given in this Subarticle provide the basis for determination of the allowable pressure at any temperature at the depth of the postulated defect during Service Conditions for which Level A and Level B Service Limits are specified. In addition to the conservatism of these assumptions, it is recommended that a factor of 2 be applied to the calculated K_f values produced by primary stresses. In shell and head regions remote from discontinuities, the only significant loadings are: (1) general primary membrane stress due to pressure; and (2) thermal stress due to thermal gradient through the thickness during startup and shutdown. Therefore, the requirement to be satisfied and from which the allowable pressure for any assumed rate of temperature change can be determined is:

$$(1) 2K_{Im} + K_{It} < K_{IR}$$

throughout the life of the component at each temperature

with K_{Im} from G-2214.1, K_{It} from G-2214.3, and K_{IR} from Fig. G-2210-1.
[98]

FIG. G-2214-2

FIG. G-2214-2

FIG. G-2214-3

FIG. G-2214-3

G-2220 NOZZLES, FLANGES, AND SHELL REGIONS NEAR GEOMETRIC DISCONTINUITIES

G-2221 General Requirements

The same general procedure as was used for the shell and head regions in G-2210 may be used for areas where more complicated stress distributions occur, but certain modifications of the procedures for determining allowable applied loads shall be followed in order to meet special situations, as stipulated in G-2222 and G-2223.

[98]

G-2222 Consideration of Membrane and Bending Stresses

(a) Equation (1) of G-2215 requires modification to include the bending stresses which may be important contributors to the calculated K_I value at a point near a flange or nozzle. The terms whose sum must be $< K_{IR}$ for Level A and Level B Service Limits are:

- (1) $2K_{Im}$ from G-2214.1 for primary membrane stress;
- (2) $2K_{Ib}$ from G-2214.2 for primary bending stress;
- (3) K_{Im} from G-2214.1 for secondary membrane stress;
- (4) K_{Ib} from G-2214.2 for secondary bending stress.

(b) For purposes of this evaluation, stresses which result from bolt preloading shall be considered as primary.

(c) It is recommended that when the flange and adjacent shell region are stressed by the full intended bolt preload and by pressure not exceeding 20% of the preoperational system hydrostatic test pressure, minimum metal temperature in the stressed region should be at least the initial RT_{NDT} temperature for the material in the stressed regions plus any effects of irradiation at the stressed regions.

irradiation at the stressed regions.

(d) Thermal stresses shall be considered as secondary except as provided in NB-3213.13(b). The K_I of Fig. G-2214-2 is not recommended for the evaluation of thermal stress because more complicated stress distributions are not adequately represented by the simplified approach of Fig. G-2214-2.

[98]

G-2223 Toughness Requirements for Nozzles

(a) A quantitative evaluation of the fracture toughness requirements for nozzles is not feasible at this time,

Page 315

but preliminary data indicate that the design defect size for nozzles, considering the combined effects of internal pressure, external loading and thermal stresses, may be a fraction of that postulated for the vessel shell. Nondestructive examination methods shall be sufficiently reliable and sensitive to detect these smaller defects.

(b) WRCB 175 provides an approximate method in Paragraph 5C(2) for analyzing the inside corner of a nozzle and cylindrical shell for elastic stresses due to internal pressure stress.

(c) Fracture toughness analysis to demonstrate protection against nonductile failure is not required for portions of nozzles and appurtenances having a thickness of 2.5 in. or less, provided the lowest service temperature is not lower than RT_{NDT} plus 60°F.

G-2300 LEVEL C AND LEVEL D SERVICE LIMITS

G-2310 RECOMMENDATIONS

The possible combinations of loadings, defect sizes, and material properties which may be encountered during Level C and Level D Service Limits are too diverse to allow the application of definitive rules, and it is recommended that each situation be studied on an individual case basis. The principles given in this Appendix may be applied, where applicable, with any postulated loadings, defect sizes, and material toughness which can be justified for the situation involved.

G-2400 HYDROSTATIC TEST TEMPERATURE

(a) For system and component hydrostatic tests performed prior to loading fuel in the reactor vessel, it is recommended that hydrostatic tests be performed at a temperature not lower than RT_{NDT} plus 60°F. The 60°F margin is intended to provide protection against nonductile failure at the test pressure.

(b) For system and component hydrostatic tests performed subsequent to loading fuel in the reactor vessel, the minimum test temperature should be determined by evaluating K_I . The terms given in (1) through (4) below should be summed in determining K_I :

(1) $1.5K_{Im}$ from G-2214.1 for primary membrane stress;

(2) $1.5K_{Ib}$ from G-2214.2 for primary bending stress;

(3) K_{Im} from G-2214.1 for secondary membrane stress;

(4) K_{Ib} from G-2214.2 for secondary bending stress.

K_I calculated by summing the four values given in (1) through (4) above, shall not exceed the applicable K_{IR} value.

(c) The system hydrostatic test to satisfy (a) or (b) above should be performed at a temperature not lower than the highest required temperature for any component in the system.

Page 316

ARTICLE G-3000 PIPING, PUMPS, AND VALVES

[98]

G-3100 GENERAL REQUIREMENTS

In the case of the materials other than bolting used for piping, pumps, and valves for which impact tests are required (NB-2311), the tests and acceptance standards of this Section are considered to be adequate to prevent nonductile failure under the loadings and with the defect sizes encountered under Level A and Level B Service Limits and testing conditions. Level C and Level D Service Limits should be evaluated on an individual case basis (G-2300).

[98]

Page 317

ARTICLE G-4000 BOLTING

[98]

G-4100 GENERAL REQUIREMENTS

In the case of bolting materials for which impact tests are required, the tests and acceptance standards of this Section are considered to be adequate to prevent nonductile failure under the loadings and with the defect sizes encountered under Level A and Level B Service Limits and testing conditions. Level C and Level D Service Limits should be evaluated on an individual case basis (G-2300). Welding Research Council Bulletin 175 (WRCB 175) "PVRC Recommendations on Toughness Requirements for Ferritic Materials," provides procedures in Paragraph 7 for evaluating various defect sizes and associated toughness levels in bolting materials.

APPENDIX J OWNER'S DESIGN SPECIFICATIONS FOR CORE SUPPORT STRUCTURES

Page 319

ARTICLE J-1000 OWNER'S DESIGN SPECIFICATIONS FOR CORE SUPPORT STRUCTURES

J-1100 INTRODUCTION

J-1110 OBJECTIVE

The objective of this Appendix is to provide a guide for Owners (NCA-3210) or their agents in the preparation of Design Specifications for core support structures. Desirably, such Design Specifications should be as uniform throughout the nuclear industry as is reasonably attainable. Such uniformity is helpful in promoting adequacy of coverage and clarity of intent.

J-1120 SCOPE OF DESIGN SPECIFICATIONS

The Design Specifications shall contain sufficient detail to provide a complete basis for the construction of the core support structure.

J-1130 FORMAT AND TERMINOLOGY USED IN DESIGN SPECIFICATIONS

J-1131 Format

The Design Specifications shall be organized in a logical manner and be free from ambiguity. All information and requirements contained in the specifications which are beyond the jurisdiction of Subsection NG should be so identified.

J-1132 Outline of Design Specifications

A suggested core support structures Design Specifications outline is:

- (a) Plant Designation and Owner
- (b) Definition of Terms
- (c) General Information
- (d) Specific Information:
 - (1) Boundaries of jurisdiction
 - (2) Materials
 - (3) Loading criteria (NG-3110)
 - (4) Maximum deformation limits, where applicable
- (e) Requirements Beyond the Jurisdiction of this Section
- (f) Design Specifications Certification

J-1133 Terminology

Nomenclature, definitions, and symbols used shall be in agreement with Subsection NG. Where additional terms, definitions, or expressions are required, they should be clearly defined, explained, and adequately referenced.

J-1140 DISTRIBUTION OF COPIES OF DESIGN SPECIFICATIONS

Copies of the Design Specifications shall be filed in accordance with NCA-3256.

J-1200 INFORMATION TO BE INCLUDED

J-1210 GENERAL INFORMATION

The Design Specifications shall include the information designated in (a) through (h) below:

(a) identification of the core support structures, as determined by their function and operating conditions [Structures whose purpose is only to limit the motion of the core following the postulated occurrence of a failure in the structure normally supporting the core are not considered core support structures. They are normally designed to meet deformation limits (J-1224) for this postulated condition and are not intended to meet the stress limits of NG-3200.];

Page 322

(b) delineation of those internal structures which are required to be analyzed in order to ensure the structural integrity of the mating core support structures;

(c) nominal environmental conditions, such as temperature, pressure, and fluid chemistry;

(d) stipulation of handling, storage, shipping, and delivery technical requirements (identified as non-Code requirements);

(e) procedure for review and certification of the Design Report by those responsible for the Design Specifications;

(f) identification of the location of core support structure installation;

(g) procedure for handling various data reports, particularly with respect to transmittal to enforcement authorities;

(h) certification of the Design Specifications.

J-1220 SPECIFIC INFORMATION

J-1221 Boundaries of Jurisdiction

The boundaries of the core support structures and their relationship to the support and restraint of the core shall be clearly defined through the use of dimensions, description, or drawings.

J-1222 Materials

The Design Specifications should provide the information relative to materials designated in (a) through (g) below:

- (a) applicable temperature limits;
- (b) any reductions to design stress intensity values, allowable stresses, or fatigue curves necessitated by environmental conditions (NCA-1130);
- (c) any restrictions on cladding materials;
- (d) materials which are acceptable from the standpoints of environment and location when cladding is required;
- (e) any restrictions on heat treating furnace atmospheres;
- (f) any requirements with respect to cleanliness;
- (g) special requirements, such as materials and testing.

J-1223 Design

J-1223.1 Design Conditions.

The Owner shall stipulate in the Design Specifications data for the following categories of operating conditions:

- (a) Level A Service Limits
- (b) Level B Service Limits
- (c) Level C Service Limits
- (d) Level D Service Limits

J-1223.2 Loading Conditions

(a) The Design Specifications need not include specific values of forces and moments at the boundaries and interfaces that result from each of the operating conditions. However, sufficient information shall be provided that will allow the designer to adequately assess the significant resultant loads. Forces and moments used in the stress analysis shall be included in the Design Report.

(b) The Design Specifications shall include information that will allow the designer to account for the loading of NG-3111, identified as to the applicable operating condition category. The information shall include a description of operating cycles and the number of occurrences of each.

J-1223.3 Loading Combinations.

For each operating condition category, the loadings of NG-3111 to be simultaneously considered shall be specified.

J-1223.4 Deformation Limits.

In addition to the stress limits given in Subsection NG, static and dynamic deformation limits shall be specified to ensure the performance of all safety related functions of the core support structure. These limits are to be those that cause loss of function and are not intended to include a margin of safety.

J-1224 Requirements Beyond the Jurisdiction of This Section

The Design Specifications shall stipulate any additional requirements which the Owner intends to be incorporated in the specific system covered by the Design Specifications or any additional requirements intended to be more specific or more restrictive than the minimum requirements of this Section.

J-1230 DESIGN SPECIFICATION CERTIFICATION

The Design Specifications shall be certified in accordance with NCA-3255.

American Society Of Mechanical Engineers SEC III D1 NMA APP K APPENDIX K TOLERANCES

Page 323

ARTICLE K-1000 TOLERANCES

[98]

K-1100 INTRODUCTION

It is recognized that design of supports is based on the use of nominal dimensions. This is not different from the design of piping or equipment which also is based on nominal dimensions. Good design practice dictates that the designer consider the degree of deviation from nominal design which can be tolerated when supports are manufactured as well as when they are installed. It is the intent of this Appendix to provide guidance to the designer as to the need for establishing such tolerances. The tolerances shown in Table K-1330-1 are for guidance and need not be measured.

[98]

[98]

K-1200 OBJECTIVE

(a) Tolerances referred to in this Appendix apply only to such values that may affect Code compliance of a support and are not already addressed in the body of the Code. Any other dimensions and tolerances associated with a support are not addressed.

(b) Since specific tolerance values are a function of the interrelationship between design, manufacturing and installation, it is impossible to provide specific values in this Appendix, with the exception of Table K-1330-1. In addition, it is recognized that there can be cost/benefit considerations associated with the establishment of tolerances.

[98]

K-1300 GENERAL REQUIREMENTS

[98]

K-1310 Material

Material supplied to an SA, SB, SFA Specification, or Table NF-3132-1 Dimensional Standards, need not have material dimensional tolerances specified by the support designer. Material provided to those specifications and standards have their own tolerances and the use of nominal dimension design is adequate. However, tolerance(s) on any manufacturing operation(s) affecting the support load capacity needs to be considered.

[98]

[98]

K-1320 Supports and Support Parts

(a) It is the responsibility of the designer to specify any tolerances associated with the support or support part. Such tolerances shall be cited in the Design Specification, Design Report, Design Drawing, Load Capacity Data Sheet or Design Report Summary.

(b) For a support or support part procured from an N-type Certificate Holder or a QSC supplier of standard supports who also provided the related Design Report or Design Report Summary, or Load Capacity Data Sheet, it is the responsibility of the Certificate Holder to assure that tolerances associated with the support or support part have been considered.

[98]

[98]

K-1330Installation

(a) Installation tolerances of supports need to be established. There are two categories of installation tolerances associated with a support. The first is a local installation tolerance affecting only the load capacity of the support itself. The second being a global installation tolerance which may affect the conclusions of the component or piping qualification.

(b) The support Design Specification, Design Report, Design Report Summary, or Load Capacity Data Sheet shall specify local installation tolerances. Table K-1330-1 provides acceptable local installation tolerances for piping supports. When piping support installation meets these tolerances, any change in the established piping support load capacity is considered minor to the point that existing load capacity calculations are adequate. Global installation tolerances should be addressed in the piping or component Design Specification or Design Report.

(c) It is the responsibility of the Construction Specification or Design Report Summary preparer to incorporate any component and piping support installation tolerances into the Construction Specification.

[98]

TABLE K-1330-1
LOCAL INSTALLATION TOLERANCES FOR PIPING SUPPORTS

Item	Total Tolerance	Configuration
<i>I. Tolerance for General Measurement/Installation</i>		
A) Deviations in the location of the centerline of any attachment to the flange centerline of building steel member(s) or piping support steel member(s); if the support drawing specifies an offset, the attachment may be relocated to any distance towards the centerline of the member to facilitate installation.	$\pm 1/4$ in.	
B) Deviation of back-to-back distance for channels with rod type component support.	$\pm 1/4$ in.	
C) Deviation in the centerline angular orientation of piping support steel members in the horizontal or vertical planes.	$\pm 2^\circ$	
D) Deviation in the centerline location of attachments between flanges of building steel members.	$\pm 1/4$ in.

SEC III D1 NMA APP L

APPENDIX L CLASS FF FLANGE DESIGN FOR CLASS 2 AND 3 COMPONENTS AND CLASS MC VESSELS

Page 331

ARTICLE L-1000 CLASS FF FLANGES - INTRODUCTION

L-1100 GENERAL REQUIREMENTS

L-1110 ACCEPTABILITY

The requirements for acceptability of Class FF flange design are that the general design requirements of Subsections NC, ND, or NE and the specific requirements of this Appendix are met.

L-1120 DEFINITION OF CLASS FF FLANGES

Class FF flanges are circular flanges having flat faces which are either bolted directly together or are separated by a metal spacer such that there is metal to metal contact between the flange faces and the metal spacer initially or after the flanges have been bolted up.

ARTICLE L-2000 CLASS FF FLANGES - MATERIALS

L-2100 MATERIAL REQUIREMENTS

The rules of Article XI-2000 apply.

ARTICLE L-3000 CLASS FF FLANGES - DESIGN

L-3100 GENERAL REQUIREMENTS

L-3110 SCOPE

The rules in this Appendix apply to circular, bolted flanged connections where the assemblage is comprised of identical or nonidentical flange pairs, and where the flanges are flat faced and are in uniform metal-to-metal contact across their entire face during assembly before the bolts are tightened or after a small amount of preload is applied to compress a gasket. The rules also apply when a pair of identical flat faced flanges are separated by a metal spacer. The rules are not intended for cases where the faces are intentionally made nonparallel to each other such that initial contact is at the bore.

Construction details for attachment and configuration of the flange are not covered in this Appendix. Minimum weld sizes and geometric limitations given in Fig. XI-3120-1 and Fig. NC-4243-2, Fig. ND-4243-1, or Fig. NE-4243-1, as applicable, apply to Appendix L flanges. Similarly, when applying the rules of this Appendix, use of the graphs in Appendix XI for obtaining applicable design parameters is necessary; namely, Figs. XI-3240-1 through XI-3240-6.

L-3120 ASSUMPTIONS AND LIMITATIONS OF RULES

It is assumed that a self-sealing gasket is used approximately in-line with the wall of attached pipe or vessel. The rules provide for hydrostatic end loads only and assume that the gasket seating loads are small and may in most cases be neglected. It is also assumed that the seal generates a negligible axial load under operating conditions. If such is not the case, allowance shall be made for a gasket load H_G dependent on the size and configuration of the seal and design pressure. Proper allowance shall be made if connections are subject to external forces other than external pressure.

L-3130 FATIGUE CONSIDERATIONS

As with flanges with ring type gaskets, the stress in the bolts may vary appreciably with pressure. There is an additional bolt stress generated due to a prying effect resulting from the flanges interacting beyond the bolt circle. As a result, fatigue of the bolts and other parts comprising the flanged connection may require consideration and adequate pretensioning of the bolts may be necessary. It is important to note that the operating bolt stress is relatively insensitive to changes in prestress up to a certain point and that thereafter the two stresses are essentially the same. This is a desirable characteristic of Appendix L flanges; it means that if the assembly stress (prestress) in the bolts is close to the operating design stress σ_b , then subsequent applications of pressure loadings ranging from zero to full load will have no significant effect on the actual operating stress in the bolts.

Unlike Appendix XI flanges and their bolts which are stressed during assembly (although some readjustment in the stresses may occur during pressurization), Appendix L flanges become stressed during pressurization; however, the effect of pressurization on the operating stress in the bolts depends upon the extent to which the bolts are stressed during assembly.

L-3140 ANALYTICAL APPROACHES

In the case of identical flange pairs, the analytical procedure described in this Appendix considers the flanges to be continuous, annular plates whose flexural characteristics can be approximated by beam theory by considering the flanges to be comprised of a series of discrete, radial beams. For nonidentical flange pairs, beam theory is supplemented by the theory of rigid body rotation so as to preserve equilibrium of moments and forces. Moments associated with beam theory are designated as *balanced moments*, whereas moments used when the theory of rigid body rotations is applied are designated as *unbalanced moments*. Balanced and

unbalanced moments are designated M_b and M_u respectively. When no subscript appears, a balanced moment is intended, i.e., in the equations for the analysis of identical flange pairs (L-3242).

L-3150 REDUCTION IN CONTACT FORCES

A reduction in flange-to-flange contact forces beyond the bolt circle occurs when the flanges are stiff with respect to the bolting and, in the extreme, flange separation occurs. The rules in this Appendix provide little insight into the problem except when the reduction in the contact force is due to the flange-hub interaction moment. The problem is considered to be of little practical significance when the nuts are tightened during assembly using ordinary wrenching techniques.

L-3160 TANGENTIAL CONTACT BETWEEN FLANGES OUTSIDE THE BOLT CIRCLE

The design procedure is based on the assumption that the flanges are in tangential contact at their outside diameter or at some lesser distance h_C from the bolt circle. [See L-3221(b) and L-3260 when

$$h_C < h_{Cmax}$$

for additional requirements.] The diameter of the circle where the flanges are in tangential contact is a design variable; the smaller the diameter of the contact circle

$$C + 2h_C$$

the greater the required prestress in the bolts, the higher the ratio of prestress to operating bolt stress, S_f/σ_b , and the smaller the flange separation at the gasket. The requirement of tangential contact, even when it is assumed to occur at the outside diameter

$$(C + 2h_{Cmax})$$

of the flanges, automatically yields a high ratio of S_f/σ_b which means that the possibility of flange separation or an appreciable decrease in the flange-to-flange contact forces is no longer a problem even when the flanges are stiff with respect to the bolts.

L-3170 RELATIVE STIFFNESS OF FLANGES AND BOLTS

The equation for the calculated strain length l of the bolts is generally applicable. However, variations in the thickness of material actually clamped by each bolt, such as sleeves, collars, or multiple washers placed between a flange and the bolt heads or nuts, or by counterboring, must be considered in establishing a value of l for use in the design equations. A large increase in l may cause the flanges to become abnormally stiff with respect to such bolts and the provision of tangential contact may not yield a sufficiently high value of the ratio S_f/σ_b unless h_C is reduced to cause an increase in the ratio.

L-3180 COMBINED STRESSES

Most of the calculated stresses are bending only, so that tensile and compressive stresses of the same magnitude occur on opposite surfaces at the point under consideration. However, when a membrane stress occurs in conjunction with a bending stress, the combined stress represents the maximum absolute value at the point and may be tension or compression (denoted by a - sign).

L-3190 NOTATION

L-3191 Symbols

The symbols described below are used in the formulas for the design of flanges.

A	= outside diameter of flange, in.
A_b	= cross-sectional area of the bolts using the root diameter of the thread or least diameter of unthreaded portion, if less, sq in.
A_m	= total required cross-sectional area of bolts, taken as the greater of A_{m1} and A_{m2} , sq in.

A_{m1}

= total cross-sectional area of bolts at root of thread or section of least diameter under stress, required for the opening conditions, sq in.

$$= W_{m1}/S_b$$

A_{m2}

= total cross-sectional area of bolts at root of thread or section of least diameter under stress, required for gasket seating, sq in.

$$= W_{m2}/S_a$$

Page 338

$\overline{AR}$

= bolt hole aspect ratio used in calculating bolt hole flexibility factor r_B

$$= \frac{nD}{\pi C}$$

a

= shape factor

$$= (A + C)/2B_1$$

B

= inside diameter of flange, in. When B is less than $20g_1$, it will be optional for the designer to substitute B_1 for B in the formula for longitudinal stress S_H

B_1

= $B + g_1$ for loose type flanges and for integral type flanges that have calculated values h/h_0 and g_1/g_0 which would indicate an f value of less than 1.0, although the minimum value of f permitted is 1.0

= $B + g_0$ for integral type flanges when f is equal to or greater than one

= B for Category 3 (loose type) flanges

b

= effective gasket or joint-contact-surface seating width, in. [see Note 1, XI-3221.1]

b_0

= basic gasket seating width, in. (from Table XI-3221.1-2)

C

= bolt circle diameter, in.

C_1

= factor

$$= - \left(0.748 - 1.567 J_S \log \frac{A}{B_1} \right) \div (1 + 1.3 J_S) \quad (1)$$

$$C_2 = \text{factor} \quad (1)$$

$$= \left[\frac{\pi}{32} (P B_1^3) - 1.3 J_P M_P \right] \div (1 + 1.3 J_S) \quad (2)$$

$$C_3 = \text{factor} \quad (2)$$

$$= - \left(0.575 - 1.206 J_S \log \frac{A}{B_1} \right) \div (J_S + t_1^3 / F_1') \quad (3)^1$$

$$C_4 = \text{factor} \quad (3)^1$$

$$= - (J_P M_P) \div (J_S + t_1^3 / F_1') \quad (4)^1$$

$$c = \text{basic dimension used for the minimum sizing of welds, in., equal to } t_n \text{ or } t_p \text{ whichever is less} \quad (4)^1$$

$$D = \text{diameter of bolt hole, in.}$$

$$d = \text{factor}$$

¹ $C_3 = C_4 = 0$ when $F_1' = 0$.

$$d = \frac{U}{V} h_0 g_0^2 \text{ for integral type flanges}$$

$$d = \frac{U}{V_L} h_0 g_0^2 \text{ for loose type flanges}$$

E = modulus of elasticity of flange material, corrected for operating temperature (see Section II, Part D, Subpart 2, Tables TM)

E_I^* = factor
 $= E_I t_I^3$

E_{II}^* = factor
 $= E_{II} t_{II}^3$

e = factor

$$= \frac{F}{h_0} \text{ for integral type flanges}$$

$$= \frac{F_L}{h_0} \text{ for loose type flanges}$$

F = factor for integral type flanges (from Fig. XI-3240-2)

F_L = factor for loose type flanges (from Fig. XI-3240-4)

$$F' = g_0^2 (h_0 + Ft) / V \text{ for Category 1,} \\ \text{Group 1 assembly} \quad (5a)$$

$$F' = g_0^2 (h_0 + F_L t) / V_L \text{ for Category 2,} \\ \text{Group 1 assembly} \quad (5b)$$

$$F' = 0 \text{ for Category 3, Group 1 assembly} \quad (5c)$$

$$F'_1 = g_0^2 (h_0 + Ft_1) / V \text{ for Category 1,} \\ \text{Group 3 assembly} \quad (6a)$$

$$F'_1 = g_0^2 (h_0 + F_L t_1) / V_L \text{ for Category 2,} \\ \text{Group 3 assembly} \quad (6b)$$

$$F'_1 = 0 \text{ for Category 3, Group 3 assembly} \quad (6c)$$

f	= hub stress correction factor for integral flanges from Fig. XI-3240-6. (When greater than 1, this is the ratio of the stress in the small end of hub to the stress in the large end.) (For values below limit of the Figure, use $f=1$.)
G	= diameter at location of gasket load reaction, in. = mean diameter of gasket, in.
g_0	= thickness of hub at small end, in.
g_1	= thickness of hub at back of flange, in.
H	= total hydrostatic end force, lb = $0.785 G^2 P$
H_C	= contact force between mating flanges, lb
H	

	$= 0.785 B^2 P$
H_G	= gasket load due to seating pressure, plus axial force generated by self-sealing of gasket, lb
H_p	= total joint-contact-surface compression load, lb $= 2b \times 3.14 GmP$
H_T	= difference between total hydrostatic end force and the hydrostatic end force on area inside of flange, lb $= H - H_D$
h	= hub length, in.
h_C	= radial distance from bolt circle to flange-spacer or flange-flange bearing circle where tangential contact occurs. Tangential contact exists from the selected value of h_C to h_{Cmax} , in.
h_{Cmax}	= radial distance from bolt circle to outer edge of flange or spacer, whichever is less, in.
h_D	= radial distance from the bolt circle, to the circle on which H_D acts, as prescribed in Table XI-3230-1, in.
h_G	= radial distance from gasket load reaction to the bolt circle, in.

$$= \frac{C - G}{2}$$

h_0	= factor, in. $= \sqrt{Bg_0}$
h_T	= radial distance from the bolt circle to the circle on which H_T acts as prescribed in Table XI-3230-1, in.

$$J_P = \frac{1}{B_1} \left[\frac{h_D}{\beta} + \frac{h_C}{a} \right] + \pi r_B$$

$$J_S = \frac{1}{B_1} \left[\frac{2h_D}{\beta} + \frac{h_C}{a} \right] + \pi r_B$$

K = ratio of outside diameter of flange to inside diameter of flange

$$= A/B$$

L = factor

$$= \frac{te + 1}{T} + \frac{t^3}{d}$$

l = calculated strain length of bolt

$$= 2t + t_s + (1/2)d \text{ for each threaded end for a Group 1 assembly}$$

$$= t_1 + t_{11} + (1/2)d \text{ for each threaded end for a Group 3 assembly}$$

M_b = balanced moment acting at diameter B_1 of flange, in.-lb

M_D = component of moment due to H_D , in.-lb

$$= H_D h_D$$

M_G = component of moment due to H_G , in.-lb

$$= H_G h_G$$

M_H = moment acting on end of hub, pipe, or shell, at its junction with back face of flange ring, in.-lb

M_P = moment due to $H_D H_P H_G$, in.-lb

=

$$H_D h_D + H_T h_T + H_G h_G$$

M_S = total moment on flange ring due to continuity with hub, pipe, or shell, in.-lb

	$= M_H + Ql/2$ where
t	= thickness of the flange under consideration (t , t_p , or t_{fl} , as applicable)
M_T	= component of moment due to H_T , in.-lb $= H_T h_T$
M_u	= unbalanced moment acting at diameter B_1 of flange, in.-lb
m	= gasket factor; obtain from Table XI-3221.1-1 [see Note 1, XI-3221.1]
N	= width, in., used to determine the basic gasket seating with b_0 based upon the possible contact width of the gasket (see Table XI-3221.1-2)
n	= number of bolts
P	= design pressure, psi
Q	= shear force between flange ring and end of hub, pipe, or shell, positive as indicated in Fig. L-3191-2 sketch (b), lb
R	= radial distance from bolt circle to point of intersection of hub and back of flange, in. For integral and hub flanges,

$$R = \frac{C - B}{2} - g_1$$

FIG. L-3191-1 BOLT HOLE FLEXIBILITY FACTOR

FIG. L-3191-1 BOLT HOLE FLEXIBILITY FACTOR

$$r_B = \frac{1}{n} \left(\frac{4}{\sqrt{1 - \overline{AR}^2}} \tan^{-1} \sqrt{\frac{1 + \overline{AR}}{1 - \overline{AR}}} - \pi - 2\overline{AR} \right)$$

(See Fig. L-3191-1 for a curve of nr_B vs $\overline{AR}$. In the above equation for r_B $\tan^{-1}$ must be expressed in radians.)

r_E

= elasticity factor

	= modulus of elasticity of flange material divided by modulus of elasticity of bolting material, corrected for operating temperature (see Section II, Part D, Subpart 2, Tables TM)
r_S	= initial bolt stress factor
	= $1 - S_f/\sigma_b$
S_a	= allowable bolt stress at atmospheric temperature, psi (given in Section II, Part D, Subpart 1, Table 3)
S_b	= allowable bolt stress at design temperature, psi (given in Section II, Part D, Subpart 1, Table 3)
S_f	= allowable design stress for material of flange at design temperature (operating condition) or atmospheric temperature (gasket seating), as may apply, psi (given in Section II, Part D, Subpart 1, Tables 1A and 1B)
S_n	= allowable design stress for material of nozzle neck, vessel or pipe wall, at design temperature (operating condition) or atmospheric temperature (gasket seating), as may apply, psi (given in Section II, Part D, Subpart 1, Tables 1A and 1B)
S_H	= calculated longitudinal stress in hub, psi
S_i	= initial bolt stress (always less than S_b), psi
S_R	= calculated radial stress in flange, psi
S_T	= calculated tangential stress in flange, psi
T	= factor involving K (from Fig. XI-3240-1)
t	= flange thickness of an identical flange pair in a Group 1 assembly, in.
t_1	= thickness of the nonreducing flange in a Group 3 assembly (see L-3231), in.
t_{II}	= thickness of the reducer or flat circular head in a Group 3 assembly (see L-3231), in.
t_i	= two times the thickness g_o , when the design is calculated as an integral flange, in., or two times the thickness, in., of shell or nozzle wall required for internal pressure, when the design is calculated as a loose flange, but not less than $\frac{1}{4}$ in.
t_n	= nominal thickness of shell or nozzle wall to which flange or lap is attached, in.

FIG. L-3191-2 FLANGE DIMENSIONS AND FORCES

FIG. L-3191-2 FLANGE DIMENSIONS AND FORCES

t_s	= thickness of spacer, in.
U	= factor involving K (from Fig. XI-3240-1)
V	= factor for integral type flanges (from Fig. XI-3240-3)
V_L	= factor for loose type flanges (from Fig. XI-3240-5)
W	= flange design bolt load, for the operating conditions or gasket seating, as may apply, lb (see L-3220)
W_{ml}	= minimum required bolt load for the operating conditions, lb (see L-3220)
w	= width, in., used to determine the basic gasket seating width b_g based upon the contact width between the flange facing and the gasket (see Table XI-3221.1-2)
X	= factor = $E_I^*/(E_I^* + E_{II}^*)$
Y	= factor involving K (from Fig. XI-3240-1)
y	= gasket or joint-contact-surface unit seating load, psi (see footnote 1, XI-3221.1)
Z	= factor involving K (from Fig. XI-3240-1)
β	= shape factor for full face metal-to-metal contact flanges = $(C + B_1)/2B_1$
θ_A	= slope of flange face at outside diameter, rad
θ_B	= slope of flange face at inside diameter, rad
θ_{rb}	= change in slope which flange pair undergoes due to an unbalanced moment, rad

L-3192 Subscripts

Subscripts I and II where noted are used to distinguish between the flanges in a nonidentical flange pair (Group 2 or 3 assemblies). B_1 without a subscript always refers to Flange I (the nonreducing flange) in a Group 2 or 3 assembly.

L-3193 Based on Nonreducing Flange

Unless otherwise noted, B_1, J_S, J_P , and F_1' [Eqs. (6a), (6b), and (6c) of L-3191] and M_P are based on the dimensions of the nonreducing flange (Flange I) in a Group 2 or 3 assembly.

L-3194 Logarithms

All logarithms are to base 10.

L-3200 DESIGN OF FLANGES AND BOLTING

L-3210 ESTIMATING FLANGE THICKNESSES AND BOLTING

L-3211 Equations for Trial Flange Thickness and Bolting

The following simple equations are offered for calculating approximate values of t , t_p , t_{II} , and A_b before applying the rules in L-3220 through L-3260. The equations are not intended to replace the rules; however, they should significantly reduce the amount of work required to achieve a suitable design. Since the flanges are in metal-to-metal contact and interact, the stresses in one flange are influenced by the stiffness of the mating flange and theoretically an unlimited number of designs can be found which satisfy the rules. In practice, however, economics, engineering judgment, and dimensional constraints will show which is the "best" design. It should be noted that the equations in Table L-3212-1 assume that both flanges comprising an assembly have essentially the same modulus of elasticity and allowable stress.

$$t_a = 2.45 \sqrt{\frac{M_p}{(\pi C - nD) S_f}} \quad (7)$$

$$t_b = 0.56 B_1 \sqrt{P / S_f} \quad (8)$$

$$t_c = \text{greater of } t_a \text{ or } t_b$$

$$t_d = t_a + \frac{(B_1 - B_{II})}{(B_1 - 0.5C)} (t_b - t_a) \quad (9)$$

$$t_e = t_a \text{ when } t_b < t_a$$

$$t_e = t_d \text{ when } t_b > t_a$$

$$A_b' = [H + 2M_p / (A - C)] \div S_b \quad (10)$$

$$t_f = 2.45 \sqrt{\frac{H_1 l_1 + H_2 l_2}{(\pi C - nD) S_f}} \quad (11)$$

$$A_b^* = 0.95 \left[\frac{2(H_1 l_1 + H_2 l_2)}{(A - C)} + 0.785 G^2 P \right] \div S_b \quad (12)$$

(7-12)

where

$$H_1 = 0.785 B_{II}^2 P$$

Page 343

$$H_2 = 0.785 (G^2 - B_{II}^2) P$$

$$l_1 = (C - B_{II})/2$$

$$l_2 = (C - G)/2 + (G - B_{II})/4$$

$$t_g = \text{smaller of } t_c \text{ or } t_f$$

TABLE L-3212-1
TRIAL FLANGE THICKNESS AND AREA OF BOLTING FOR VARIOUS GROUPS OF
ASSEMBLIES AND FLANGE CATEGORIES

Group (Assembly)	Category of Flanges		Suggested Trial Values		
	Nonreducing	Reducing	t or t_I	t_{II}	A_b
1	1 or 2	...	$0.9t_a$	...	$0.9A_b'$
	3	...	t_a	...	A_b'
2	1 or 2	1 or 2	t_a	t_e	A_b'
	3	3	$1.1t_a$	$1.1t_c$	$1.1A_b'$
	3	1 or 2	t_a	t_c	A_b'
	1 or 2	3	$1.1t_g$	$1.1t_g$	$A_b'^*$
3	1, 2, or 3	...	$1.1t_a$	$1.1t_c$	$1.05A_b'$

TABLE L-3212-1 TRIAL FLANGE THICKNESS AND AREA OF BOLTING FOR VARIOUS GROUPS OF ASSEMBLIES AND FLANGE CATEGORIES

L-3212 Trial Values of t , t_I , t_{II} , and A_b

The simple equations given in Table L-3212-1 should yield relatively good trial values of t , t_I , t_{II} , and A_b but they do not assure that the "first trial design" will meet the requirements of L-3240 through L-3250. As a result, it becomes necessary to select new trial values and reanalyze. In order to assist the designer in selecting the second trial values, the following comments concerning the behavior of different groups of Class FF flanges are offered.

(a) The hub of a Category 1 or 2 flange of a Group 1 assembly reduces the radial stress at the bolt circle (due to a negative hub-flange interaction moment) and the longitudinal hub stress. As a result, a pair of Category 1 or Category 2 flanges will be thinner than a pair of identical Category 3 flanges.

(b)

(b) Increasing the thickness of the reducing flange of a Group 3 assembly, when the nonreducing flange is Category 1 and 2, generally reduces the significant stresses in both flanges comprising the assembly. When the stress in Flange I (nonreducing) is excessive, increasing t_I will generally be more effective in reducing the stresses; however, a nominal increase of the stresses in Flange II will occur due to the additional restraint provided by increasing t_I . When the stress in Flange I is excessive and only marginally acceptable in Flange II, both t_I and t_{II} should be increased with the emphasis placed on t_I .

(c) A Category 3 reducing flange bolted to a Category 1 or 2 nonreducing flange produces a large overturning moment which tends to rotate Flange I in a negative direction. As a result, the radial stress at the bolt circle in Flange I will often be excessive due to a large, positive hub-flange interaction moment. As a result, it is usually necessary to increase t_I so that $t_I = t_{II}$. The same problem does not occur when Flange I is Category 3 since there exists no hub-flange interaction moment. When Flange I is an optional type treated as a loose type (Category 3), a hub-flange interaction moment actually exists but is disregarded in the analysis by assigning the flange to Category 3.

(d) When the longitudinal hub stress of a Category 1 or 2 flange is excessive, it can be reduced by increasing the size of the hub, or g_0 when $g_1 = g_0$; however, this will cause an increase in the radial stress at the flange-hub junction. When S_H is excessive and S_R is marginally acceptable, an increase in the thickness of the flange is indicated in which case it may or may not be necessary to alter the size of the hub.

(e) When the longitudinal stress in the hub of the nonreducing flange of a Group 2 or Group 3 assembly is low compared to the allowable stress and the radial stress at the bolt circle is excessive, increasing S_H by making the hub smaller (more flexible) will often reduce the radial stress at the bolt circle to S_r . If it does not, an increase in t_I is indicated.

Page 344

L-3220 BOLT LOADS

L-3221 Required Bolt Load

The flange bolt load used in calculating the required cross-sectional area of bolts shall be determined as follows.

(a) The required bolt load for the operating condition W_{m1} shall be sufficient to resist the sum of the hydrostatic end force H exerted by the maximum allowable working pressure on the area bounded by the diameter of the gasket reaction, and the contact force H_C exerted by the mating flange on the annular area where the flange faces are in contact. To this shall be added the gasket load H_G for those designs where gasket seating requirements are significant.

(b) Before the contact force H_C can be determined, it is necessary to obtain a value for its moment arm h_C . Due to the interaction between bolt elongation and flange deflection, h_C involves the flange thickness t , operating bolt stress σ_b , initial bolt prestress factor r_s , and calculated strain length l , elasticity factor r_E , and total moment loading on the flange. This Article is based on starting a design by assuming a value for h_C and then calculating the value of the initial bolt stress S_i which satisfies the assumption.

Although the distance h_C from the bolt circle to the flange-to-flange contact circle is a design variable, for the purpose of this Article the use of

$$h_C < h_{Cmax}$$

to optimize stresses is considered to be a special situation requiring controlled bolt tightening and verification (see L-3260). Except in special instances, setting h_C equal to h_{Cmax} should be satisfactory. It is inherent in the computational process that the flanges will be in tangential contact between the selected bearing circle

$$C + 2h_C$$

and the outside diameter of the flanges

$$C + 2h_{Cmax}$$

(c) The hub-flange interaction moment M_S , which acts on the flange, is expressed by Formulas (13), (25), and (26); for Category 3 flanges

$$M_S = 0$$

The contact force H_C is determined by Formulas (15) or (33).

(d)

(d) The required bolt load for operating conditions is determined in accordance with the following formula:

$$W_{ml} = H + H_C + H_G$$

L-3222 Total Required and Actual Bolt Areas, and Flange Design Bolt Load

The total required cross-sectional area of bolts A_M equals W_{ml}/S_b . A selection of bolts to be used shall be made such that the actual total cross-sectional area of bolts A_b will not be less than A_m . The flange design bolt load W shall be taken equal to W_{ml} .

L-3230 CLASSIFICATION OF ASSEMBLIES AND CATEGORIZATION OF INDIVIDUAL FLANGES

It is necessary to classify the different types of flanged assemblies and to further categorize each flange which comprises the assembly under consideration.

L-3231 Classification of a Class FF Flange Assembly

Since the flanges comprising an assembly are in contact outside the bolt circle, the behavior of one flange is influenced by the stiffness of the other. For the purpose of computation it is helpful to classify an assembly consisting of different types of flanges according to the way the flanges influence the deformation of the assembly.

Page 345

NOTES:

(2) Permitted weld details are in accordance with Figs. XI-3120-1 and NC-4243-2, ND-4243-1 or NE-4243-1, as applicable.

**FIG. L-3230-1 GROUP 1 FLANGE ASSEMBLY
(IDENTICAL FLANGE PAIRS)**

NOTES:

- (1) Category 1 flanges illustrated. Categories II and III permitted.
- (2) For purposes of analysis of Flange II by method in L-3243(a), assume $A_{II} = G_{II} = C_{II} = B_1$
- (3) $B_{II} > C/2$
- (4) Permitted weld details are in accordance with Figs. XI-3120-1 and NC-4243-2, ND-4243-1 or NE-4243-2, as applicable.
- (5) See L-3192 and L-3193.

FIG. L-3230-2 GROUP 2 FLANGE ASSEMBLY

FIG. L-3230-2 GROUP 2 FLANGE ASSEMBLY

L-3231.1 Group 1 Assembly.²

A pair of flanges which are bolted together and which are nominally identical with respect to shape, dimensions, physical properties, and allowable stresses³ except that one flange of the pair may contain a gasket groove. (A Group I assembly is also referred to as an identical flange pair.) Figure L-3230-1 illustrates configuration of a Group I assembly.

L-3231.2 Group 2 Assembly.

Any assemblage which does not fit the description of Group 1 where, in the case of reducers, the inside diameter of the reducing flange exceeds one-half of the bolt circle diameter. Figure L-3230-2 illustrates configuration of a Group 2 assembly.

L-3231.3 Group 3 Assembly.

Any assemblage consisting of a reducer or a flat circular head without an opening or with a central, reinforced opening provided the diameter of the opening in the reducing flange or flat cover is less than one-half of the bolt circle diameter. In the analysis the reducing flange is considered to be the equivalent of a flat circular head without an opening. Figure L-3230-3 illustrates configuration of a Group 3 assembly.

L-3232 Categorization of a Class FF Flange

In addition to classifying an assembly, the individual flanges (except the reducing flange or flat circular head) must be categorized for the purpose of computation as loose type, integral type, or optional type. This can be done using XI-3120; Fig. XI-3120-1 is suitable by considering the flanges as flat faced (as a result of removing the raised gasket surface by machining and recessing the gasket in a groove) and by adding a flange-to-flange contact force H_C at some distance h_c outside the bolt circle. Since certain design options exist depending upon the category of the flange, the following categories include both the type of flange and the various design options.

(a) *Category 1 Flange.* An integral flange or an optional flange calculated as an integral flange.

(b) *Category 2 Flange.* A loose type flange with a hub where credit is taken for the strengthening effect of the hub.

² A Class FF flange bolted to a rigid foundation may be analyzed as a Group 1 assembly by substituting 2 for 1 in Eq. (18) of L-3242.

³ Where the flanges are identical dimensionally and have the same elastic modulus E , but have different allowable stresses S_f , the assembly may be analyzed as a Group I assembly provided the calculated stresses are evaluated against the lower allowable stress.

NOTES:

- (1) Category I flange illustrated. Categories II and III permitted.
- (2) $B_{II} \leq C/2$
- (3) Permitted weld details are in accordance with Figs. XI-3120 and NC-3225-3.
- (4) See L-3192 and L-3193.

FIG. L-3230-3 GROUP 3 FLANGE ASSEMBLY

FIG. L-3230-3 GROUP 3 FLANGE ASSEMBLY

(c) *Category 3 Flange*. A loose type flange with a hub where no credit is taken for the strengthening effect of the hub, a loose type flange without a hub, or an optional-type flange calculated as a loose type without a hub. Substitute B for B_1 in the applicable equation for this category of flange.

L-3240 FLANGE ANALYSIS

L-3241 General Method

(a) In order to calculate the stresses in the flanges and bolts of a flanged assembly, classify the assemblage in accordance with L-3231 and then categorize each flange per L-3232.

(b) The method of analyzing various groups and categories of flanges is basically the same. Although many equations appear to be identical, subtle differences do exist and care must be exercised in the analysis. To minimize the need for numerous footnotes and repetitive statements throughout the text, the formulas to be used in analyzing the various groups of assemblies and categories of flanges are given in Table L-3240-1.

Page 347

TABLE L-3240-1
SUMMARY OF APPLICABLE FORMULAS FOR
DIFFERENT GROUPS OF ASSEMBLIES AND
DIFFERENT CATEGORIES OF FLANGES

Group	Category [Note (1)]	Applicable Formulas
1	1	(5a), (13)–(19), (20a), (21a), (22a)
1	2	(5b), (13)–(19), (20b), (21b), (22b)

TABLE L-3240-1 SUMMARY OF APPLICABLE FORMULAS FOR DIFFERENT GROUPS OF ASSEMBLIES AND DIFFERENT CATEGORIES OF FLANGES

In general, the terms should be calculated in the same order as they are listed in the table. It is important to refer to the table before starting an analysis since only a limited number of the equations contained in this Article are used in the design of a particular pair of flanges. Some of the numbered equations appear in L-3191 along with general purpose, unnumbered expressions.

(c) Subscripts I and II refer to the nonreducing flange and the reducer (or flat circular head), respectively, of a Group 3 assembly and of a Group 2 assembly designed using the method of L-3243(a).

L-3242 Analysis of a Group 1 Assembly

The following equations are used for the analysis of Category 1, 2, and 3 flanges of a Group 1 assembly in accordance with Table L-3240-1.

Flange Moment Due to Flange-Hub Interaction

$$M_S = - \frac{J_P F' M_P}{t^3 + J_S F'} \quad (13)$$

(13)

Slope of Flange at Inside Diameter Times E

$$E\theta_B = \frac{5.46}{\pi t^3} (J_S M_S + J_P M_P) \quad (14)$$

(14)

Contact Force Between Flanges at h_C

$$(15) H_c = (M_p + M_s)/h_C$$

Bolt Load at Operating Conditions

$$(16) W_{ml} = H + H_G + H_C$$

Operating Bolt Stress

$$(17) \sigma_b = W_{ml}/A_b$$

Design Prestress in Bolts

$$S_i = \sigma_b - \frac{1.159h_C^2 (M_P + M_S)}{at^3 lr_E B_1} \quad (18)$$

(18)

Radial Flange Stress at Bolt Circle

$$S_R = \frac{6(M_P + M_S)}{t^2 (\pi C - nD)} \quad (19)$$

(19)

Radial Flange Stress at Inside Diameter

$$S_R = - \left(\frac{2Ft}{h_0 + Ft} + 6 \right) \frac{M_S}{\pi B_1 t^2} \quad (20a)$$

$$S_R = - \left(\frac{2F_L t}{h_0 + F_L t} + 6 \right) \frac{M_S}{\pi B_1 t^2} \quad (20b)$$

$$S_R = 0 \quad (20c)$$

(20a-20c)

Tangential Flange Stress at Inside Diameter

$$S_T = \frac{tE\theta_B}{B_1} + \left(\frac{2FtZ}{h_0 + Ft} - 1.8 \right) \frac{M_S}{\pi B_1 t^2} \quad (21a)$$

$$S_T = \frac{tE\theta_B}{B_1} + \left(\frac{2F_L tZ}{h_0 + F_L t} - 1.8 \right) \frac{M_S}{\pi B_1 t^2} \quad (21b)$$

(21a-21b)

Page 348

$$S_T = \frac{tE\theta_B}{B_1} \quad (21c)$$

(21c)

Longitudinal Hub Stress

$$S_H = \frac{h_0 E \theta_B f}{0.91 (g_1 / g_0)^2 B_1 V} \quad (22a)$$

$$S_H = \frac{h_0 E \theta_B}{0.91 (g_1 / g_0)^2 B_1 V_L} \quad (22b)$$

$$S_H = 0 \quad (22c)$$

(22a-22c)

L-3243 Analysis of a Group 2 Assembly

(a) The assembly may be analyzed using a variation of the analysis for a Group 3 assembly (L-3244) that accounts for the interaction of nonidentical flanges and the stiffening effect of an integral nozzle or hub centrally located in the reducing flange.

(1) The central nozzle of Flange II with diameter B_{II} shall be assumed for analysis purposes as an Appendix XI flange with outside diameter A , bolt circle C , and gasket circle G all equal to B_1 of Flange I. See Fig. L-3230-2.

(2) In addition it is necessary to categorize the centrally located Appendix XI flange (nozzle plus the associated over plate to diameter B_1) as a Category 1, 2, or 3 flange in accordance with L-3232.

(3) The moment due to pressure shall be designated M_p' where

$$M_p' = H_D' h_D' + H_T' h_T'$$

$$H_D' = 0.785 B_{II}^2 P$$

$$H_T' = 0.785 P (B_I^2 - B_{II}^2)$$

For Category 1, 2, or 3 flanges [see (a)(2) above],

$$h_T' = \frac{B_I - B_{II}}{4}$$

For Category 1 or 2 flanges [see (a)(2) above],

$$h_D' = \frac{B_I - B_{II} - g_{I II}}{2}$$

For Category 3 flanges [see (a)(2) above],

$$h_D' = \frac{B_I - B_{II}}{2}$$

(4) The rules in L-3244 and the summary of Table L-3240-1 for the analysis of a Group 3 assembly apply to the analysis of a Group 2 assembly with the following additions and substitutions:

C_5 and C_6 and all the symbols in equations in (a) and (b) below pertain only to the centrally located Appendix XI flange [nozzle plus the associated cover of thickness t_{II} to diameter B_I defined in (1) above]. All terms in equations in (c) and (d) below, except C_5 and C_6 , refer to the nonreducing flange (Flange I). C_1 and C_2 of equations in (c) and (d) below replace C_1 and C_2 of Eqs. (1) and (2) in L-3191.

(a) Let

$$C_5 = M_P', \text{ in.-lb}$$

(b) Let

$$C_6 = \frac{0.829}{\log (B_I / B_{II})}$$

for Category 3 flanges.⁴ Let

$$C_6 = \frac{0.91 t_{II}^3 V}{L h_0 g_0^2}$$

for Category 1 or 2 flanges.⁴

(c) Let

$$C_1 = [1 - 2.095 J_S \log (A/B_1)] \div [-C_6 - 1.738 J_S]$$

(d) Let

⁴ See L-3243(a)(2).

Page 349

$$C_2 = (1.738 J_P M_P - C_5 C_6) \div (-C_6 - 1.738 J_S)$$

(e) Replace Eq. (32) with:

$$E_{II} \theta_{BII} = \frac{5.46}{\pi t_{II}^3} (J_S M_{bII} + J_P M_P) + (E_{II}^* \theta_{rbII}) / t_{II}^3$$

(f) Delete Eq. (44). Subparagraphs L-3243(a)(1), (a)(2), and (a)(3) above apply only for calculating $C_5(M_P')$ and C_6 and subsequently when using (a)(5) below for calculating the stresses in and adjacent to the nozzle in Flange II.

(5) Stresses in the centrally located nozzle of Flange II shall be calculated in accordance with the following equations after M_{SI} has been found using (a)(4) above. All terms, such as e , Y , and Z , apply to the centrally located Appendix XI flange as defined in (a)(1) and (a)(2) above.

For Category 1 or 2 flanges [(a)(2) above]:

Longitudinal Hub Stress

$$S_{H\Pi} = \frac{f(M_p' - M_{S\Pi})}{Lg_{1\Pi}^2 B_{\Pi}}$$

Radial Flange Stress Adjacent to Central Nozzle

$$S_{R\Pi} = \frac{(1.33t_{\Pi}e + 1)(M_p' - M_{S\Pi})}{Lt_{\Pi}^2 B_{\Pi}}$$

Tangential Flange Stress Adjacent to Central Nozzle

$$S_{T\Pi} = \frac{Y(M_p' - M_{S\Pi})}{t_{\Pi}^2 B_{\Pi}} - ZS_{R\Pi}$$

For Category 3 Flanges [(a)(2) above]:

Tangential Flange Stress Adjacent to Central Nozzle

$$S_{TII} = \frac{Y(M_p' - M_{SII})}{t_{II}^2 B_{II}}$$

Radial and Longitudinal Hub Stress

$$S_{RII} = 0$$

$$S_{HII} = 0$$

(6) The stresses in Flange I and the remaining stresses in Flange II shall be calculated in accordance with L-3244 except as modified by L-3243(a)(4).

(b) As an alternative to the method in (a) above and at the option of the designer, the assembly may be analyzed as if it is one flange of an identical pair in a Group 1 assembly using the procedure in L-3242. All stresses shall satisfy L-3250. The same value of h_C shall be used in both calculations and the strain length l of the bolts shall be based on the thickness of the flange under consideration. This method is more conservative and more bolting may be required than the method in (a) above.

(c) The central nozzle or opening in Flange II of a Group 2 assembly determined by the rules in (a) or (b) above meets the general requirements of this Division and of this Article. The rules for determining thickness and reinforcing requirements of NC-3225, NC-3325, ND-3325, and NE-3325, and NC-3233, NC-3333, ND-3333, and NE-3333, respectively, are not applicable.

L-3244 Analysis of a Group 3 Assembly

(a) The following equations are used for the analysis of Category 1, 2, and 3 nonreducing flanges and the reducer (or flat circular head) of a Group 3 assembly:

Rigid Body Rotation of Flanges Times E^*

$$E_I^* \theta_{rbI} = \frac{X(C_4 - C_2)}{1.206 \log (A/B_1) - XC_3 - (1 - X)C_1} \quad (23)$$

$$E_{II}^* \theta_{rbII} = - E_I^* \theta_{rbI} (E_{II}^* / E_I^*) \quad (24)$$

(23-24)

Total Flange Moment at Diameter B_1

$$(25) M_{SI} = C_3(E_I^* \theta_{rbI}) + C_4$$

$$(26) M_{SII} = C_1(E_{II}^* \theta_{rbII}) + C_2$$

Unbalanced Flange Moment at Diameter B_1

$$(27) M_{Id} = 1.206 E_I^* \theta_{rbI} \log (A/B_1)$$

$$(28) M_{IdII} = 1.206 E_{II}^* \theta_{rbII} \log (A/B_1)$$

Balanced Flange Moment at Diameter B_1

$$(29) M_{bI} = M_{SI} - M_{Id}$$

$$(30) M_{bII} = M_{SII} - M_{IdII}$$

Slope of Flange at Diameter B_1 Times E

$$E_I \theta_{BI} = \frac{5.46}{\pi t_I^3} (J_S M_{bI} + J_P M_P) + E_I^* \theta_{rbI} / t_I^3 \quad (31)$$

$$E_{II} \theta_{BII} = \frac{-1.337(M_{SII} - \pi P B_1^3 / 32)}{t_{II}^3} \quad (32)$$

(31-32)

Contact Force Between Flanges at h_C

$$(33) H_C = (M_P + M_{bI}) / h_C$$

Bolt Load at Operating Conditions

$$(34) W_{mI} = H + H_G + H_C$$

Operating Bolt Stress

$$(35) \sigma_b = W_{mI} / A_b$$

Design Prestress in Bolts

$$S_i = \sigma_b - \frac{1.159 h_C^2 (M_P + M_{bI})}{2(1 - X) a t_I^3 l r_{EI} B_I} \quad (36)$$

(36)

Radial Stress in Flange I at Bolt Circle

$$S_{RI} = \frac{6(M_P + M_{SI})}{t_I^2(\pi C - nD)} \quad (37)$$

(37)

Radial Stress in Flange I at Inside Diameter

$$S_{RI} = - \left(\frac{2Ft_I}{h_0 + Ft_I} + 6 \right) \frac{M_{SI}}{\pi B_1 t_I^2} \quad (38a)$$

$$S_{RI} = - \left(\frac{2F_L t_I}{h_0 + F_L t_I} + 6 \right) \frac{M_{SI}}{\pi B_1 t_I^2} \quad (38b)$$

$$S_{RI} = 0 \quad (38c)$$

(38a-38c)

Tangential Stress in Flange I at Inside Diameter

$$S_{TI} = \frac{t_I E_I \theta_{BI}}{B_I} + \left(\frac{2F t_I Z}{h_0 + F t_I} - 1.8 \right) \frac{M_{SI}}{\pi B_I t_I^2} \quad (39a)$$

$$S_{TI} = \frac{t_I E_I \theta_{BI}}{B_I} + \left(\frac{2F_L t_I Z}{h_0 + F_L t_I} - 1.8 \right) \frac{M_{SI}}{\pi B_I t_I^2} \quad (39b)$$

(39a-39b)

$$S_{TI} = \frac{t_I E_I \theta_{BI}}{B_I} \quad (39c)$$

(39c)

Longitudinal Hub Stress in Flange I

$$S_{HI} = \frac{h_0 E_I \theta_{BI} f}{0.91 (g_1 / g_0)^2 B_1 V} \quad (40a)$$

$$S_{HI} = \frac{h_0 E_I \theta_{BI}}{0.91 (g_1 / g_0)^2 B_1 V_L} \quad (40b)$$

$$S_{HI} = 0 \quad (40c)$$

(40a-40c)

Radial Stress in Flange II at Bolt Circle

$$S_{R\Pi} = \frac{6(M_P + M_{S\Pi})}{t_{II}^2 (\pi C - nD)} \quad (41)$$

(41)

Radial Stress in Flange II at Diameter B_1

$$S_{R\Pi} = \frac{6M_{S\Pi}}{\pi B_I t_{\Pi}^2} \quad (42)$$

(42)

Tangential Stress in Flange II at Diameter B_I

$$S_{T\Pi} = \frac{t_{\Pi} E_{\Pi} \theta_{B\Pi}}{B_I} - \frac{1.8M_{S\Pi}}{\pi B_I t_{\Pi}^2} \quad (43)$$

(43)

Radial and Tangential Stress at Center of Flange II

$$S_{R\Pi} = S_{T\Pi} = \frac{0.3094PB_I^2}{t_{\Pi}^2} - \frac{6M_{S\Pi}}{\pi B_I t_{\Pi}^2} \quad (44)$$

(44)

(b) The thickness of Flange II of a Group 3 assembly determined by the above rules shall be used in lieu of the thickness that is determined by NC-3225, NC-3325, ND-3325, and NE-3325. However, any centrally located opening in Flange II shall be reinforced to meet the rules of Appendix XIX.

⁵ The symbols for the various stresses in the case of a Group 3 assembly also carry the subscript I or II. For example, S_{II} represents the longitudinal hub stress in Flange I of the Group 3 assembly.

L-3250 ALLOWABLE FLANGE DESIGN STRESSES

The stresses calculated by the above equations, whether tensile or compressive (-), shall not exceed the following values

- (a) operating bolt stress σ_b not greater than S_b for the design value of S_j ;
- (b) longitudinal hub stress S_H not greater than S_f for Category 1 and 2 cast iron flanges except as otherwise limited by (1) and (2) below and not greater than $1.5 S_f$ for materials other than cast iron:
 - (1) longitudinal hub stress S_H not greater than the smaller of $1.5 S_f$ or $1.5 S_n$ for Category 1 flanges where the pipe or shell constitutes the hub;
 - (2) longitudinal hub stress S_H not greater than the smaller of $1.5 S_f$ or $2.5 S_n$ for integral flanges (Category 1) similar to the Appendix XI flanges shown as Fig. XI-3120-1, sketches (6), (6a), and (6b).
- (c) radial stress S_R not greater than S_j ;
- (d) tangential stress S_T not greater than S_j ;
- (e) also,

$$(S_H + S_R)/2$$

not greater than S_f and

$$(S_H + S_T)/2$$

not greater than S_j ;

- (f) S_R and S_T at the center of the reducing flange in a Group 3 assembly [see Eq. (44)] shall not exceed S_f

L-3260 PRESTRESSING THE BOLTS

The design rules of this Article provide for tangential contact between the flanges at h_{Cmax} or some lesser value h_C beyond the bolt circle. As in the case of Appendix XI flanges, a Class FF flange must be designed so that the calculated value of the operating bolt stress σ_b does not exceed S_b . Also, as in the case of Appendix XI flanges, ordinary wrenching techniques without verification of the actual initial bolt stress (assembly stress) is considered to meet all practical needs with control and verification reserved for special applications. For the purposes of this Article, the use of

$$h_C < h_{Cmax}$$

to optimize stresses is considered to be a special application unless it is also shown that all of the requirements of this Article are also satisfied when

$$h_C = h_{Cmax}$$

APPENDIX M RECOMMENDATIONS FOR CONTROL OF

WELDING, POSTWELD HEAT TREATMENT, AND NONDESTRUCTIVE EXAMINATION OF WELDS

Page 353

ARTICLE M-1000 RECOMMENDATIONS FOR CONTROL OF WELDING, POSTWELD HEAT TREATMENT, AND NONDESTRUCTIVE EXAMINATION OF WELDS

M-1100 INTRODUCTION

M-1110 SCOPE

This Appendix provides recommendations for control of welding, postweld heat treatment, and nondestructive examination of welds. The purpose of this Appendix is to identify the areas that should be controlled. It should not be construed that this Appendix describes the only controls that are necessary. Other controls may be necessary depending on the specific application.

M-1120 APPLICABILITY

The recommendations contained in this Appendix may be included in procedures, instructions, specifications, process sheets, shop travelers, checklists, drawings, or other documents that are part of the Quality Assurance or Control Program.

M-1200 WELDING PROCEDURE SPECIFICATIONS

M-1210 RESPONSIBILITY FOR PREPARATION

The responsibility for preparing and approving the Welding Procedure Specification, and the method of handling revisions should be defined in the Quality Assurance or Control Program.

M-1211 Content Requirements

Section IX identifies the essential and also the nonessential variables required to be included in a Welding Procedure Specification. Supplementary information that should be provided, as applicable, is listed in (a) through (k) below. This information may be provided in other specifications, drawings, or documents that are referenced in or used in conjunction with the Welding Procedure Specification, as described in M-1213:

- (a) weld joint design, including fit-up;
- (b) method of weld joint preparation;
- (c) cleaning requirements prior to welding;
- (d) purge requirements in addition to QW-408.5 of Section IX, such as oxygen content, volume changes, or time of purging prior to welding, and minimum thickness of deposited metal prior to removal or purge;
- (e) cleaning and examination requirements between weld passes;
- (f) instructions for measuring preheat and interpass temperatures;
- (g) preheat temperature control;
- (h) interpass temperature control;
- (i) temperature maintenance and control after welding;
- (j) welding current and voltage control including method and frequency of measurement;
- (k) welding technique including, as applicable, method of starts and stops, method of arc initiation, and weave or stringer bead.

M-1212 Format of Welding Procedure Specification

Welding Procedure Specifications may consist of a single document. Alternatively, there may be a general Welding Procedure Specification that applies to and is referenced by a number of detailed Welding Procedure Specifications. The general Welding Procedure Specification may also reference other specifications to define other requirements such as welding filler materials, purging, and postweld heat treatment.

Page 356

M-1213 Application of Welding Procedures

Selection of qualified welding procedures should be based on the essential variables applicable for the production weld. Any additional requirements of the Design Specification, such as component classification, applicable Code edition and addenda, fracture toughness requirements, and manufacturing considerations, should be evaluated in the selection of welding procedures for specific weld joints.

M-1300 WELDING PERFORMANCE QUALIFICATION AND ASSIGNMENT

It is necessary that a system be established to ensure that properly qualified welders and welding operators are used for specific weld joints. The system should include confirmation that the welder and welding operator qualifications are up to date and valid for the application.

M-1400 CONTROL OF WELDING

A system should be established and maintained that is capable of:

- (a) maintaining the identification of acceptable electrodes, filler metal, consumable inserts, and fluxes until consumed; and
- (b) minimizing moisture absorption of coated electrodes and of fluxes.

The system should include requirements for receiving inspection, storage, handling, use of holding ovens, control of exposure time at ambient temperature, and reconditioning.

M-1500 NONDESTRUCTIVE EXAMINATION OF WELDS

M-1510 RESPONSIBILITY FOR PREPARATION

Nondestructive examination procedures should be prepared in accordance with the requirements of the particular Article of this Section used in fabrication, including acceptance standards. The responsibility for preparation and approval of procedures and the method of handling revisions should be defined in the Quality Assurance or Control Program.

M-1520 VERIFICATION OF APPLICABILITY

Prior to assignment of nondestructive examination procedures to specific weld joints, a review should be made of the Code classification of the component and the Code edition and addenda to ensure that the type of examination, procedure and acceptance standards, frequency, and time of examination are all correct for the application.

M-1600 POSTWELD HEAT TREATMENT

A system should be established and maintained that is capable of meeting PWHT requirements for heating and cooling rates, metal temperature, metal temperature uniformity, and temperature control. The location of thermocouples, furnace loading to prevent direct impingement of flame on parts or components, and the furnace atmosphere should be considered in establishing procedures.

M-1700 EXAMINATION AND DIMENSIONAL INSPECTION

Examinations and dimensional inspections should be made to provide assurance that the requirements of this Section are met and that welding conforms with the procedures, specifications, and drawings. As applicable, consideration should be given to (a) and (b) below.

- (a) Before welding:
 - (1) material identification
 - (2) weld preparation surfaces
 - (3) cleanliness
 - (4) root opening
 - (5) offset
 - (6) alignment
 - (7) socket engagement on socket welds
- (b) After welding:
 - (1) cracks or linear indications
 - (2) rounded indications
 - (3) overlap
 - (4) undercut
 - (5) lack of required penetration
 - (6) surface finish
 - (7) weld profile

APPENDIX N DYNAMIC ANALYSIS METHODS

Page 357

ARTICLE N-1000 DYNAMIC ANALYSIS METHODS

N-1100 INTRODUCTION AND SCOPE

Section III does not require dynamic analysis. However, the design of nuclear components requires consideration of the seismic and other dynamic inputs which are defined in the Design Specifications for the component. Component design may be based on the use of static forces resulting from equivalent earthquake acceleration acting at the centers of gravity of the extended masses, or a dynamic system analysis may be used to show how seismic loading is transmitted from the defined ground motions to all parts of the buildings, structures, equipment, and components. N-1100 through N-1200 of this Appendix are presented to illustrate one or more acceptable steps for seismic dynamic analysis. It is not intended that these steps are the only acceptable ones, since the seismic dynamic analysis involves a series of steps, and some of these steps have acceptable alternative methods. Dynamic analysis in general uses techniques which are illustrated in seismic analysis. Those technical areas of dynamic analysis used in nuclear component design which are not specifically illustrated by seismic analysis are included in N-1300 through N-1700.

N-1110 DEFINITIONS AND NOTATIONS

(a) The *magnitude* of an earthquake is a measure of the size of an earthquake and is related to the energy released in the form of seismic waves. Magnitude means the numerical value on a Richter scale. The intensity of an earthquake is a measure of its effects on man, on man-built structures, and on the earth's surface at a particular location. Intensity is measured by the numerical value of the modified Mercalli scale.

(b) The *Safe Shutdown Earthquake* (SSE) is that earthquake which is based upon an evaluation of the maximum earthquake potential considering the regional and local geology and seismology and specific characteristics of local subsurface material. It is that earthquake which produces the maximum vibratory ground motion for which those structures, systems, and components important to safety are designed to remain functional.

(c) The *Operating Basis Earthquake* (OBE) is that earthquake which, considering the regional and local geology and seismology and specific characteristics of local subsurface material, could reasonably be expected to affect the plant site during the operating life of the plant.

(d) The *response spectrum* is defined as a plot of the maximum response (acceleration, velocity, or displacement) of a family of idealized linear single-degree-of-freedom damped oscillators as a function of natural frequencies (or periods) of the oscillators to a specified vibratory motion input at their supports.

(e) The *design ground response spectrum* is a smooth response spectrum obtained by analyzing, evaluating, and statistically combining a number of individual response spectra derived from the records of significant past earthquakes.

(f) The *maximum (peak) ground acceleration* (for a given site) is defined as that value of the acceleration which corresponds to zero period in the design response spectra for that site. At zero period the design response spectra acceleration is identical for all damping values and is equal to the maximum (peak) ground acceleration specified for that site.

(g) *Normal mode - time history methods* use the normal mode theory and a time history of the input motion. When normal mode theory is used, the maximum response is determined by obtaining the combined response of all individual modes at a particular time.

(h) *Direct integration - time history methods* use numerical step-by-step integration of the equations of motion of a time history of the input motion.

(i) *Equivalent statical methods* means the use of a statical loading coefficient which gives a definite upper limit to the response.

(j) *Coupled structures and plant equipment* include those structures and plant equipment which, because of their mass and stiffness properties, significantly

Page 362

influence the dynamic response of each other and must be considered together in a dynamic analysis.

(k) *Uncoupled structures and plant equipment* include those structures and plant equipment which, because of their mass and stiffness properties, do not significantly influence the dynamic response of each other and can be considered in separate dynamic analysis.

(l) *Seismic systems* are all those structures for which loads induced by earthquake should be considered.

(m) *Rigid range* is used to describe those frequencies of structures, systems, or components whose natural frequencies are greater than some value at which dynamic response acceleration is essentially the same as the impact acceleration. For example, a response to the seismic design response spectra of Figs. N-1211(a)-1 and N-1211(b)-1 has unity amplification of acceleration above 33 Hz.

(n) *Spectrum consistent time history* is a time history which is artificially generated to essentially envelop a given design response spectrum.

N-1200 SEISMIC ANALYSIS

N-1210 EARTHQUAKE DESCRIPTION

N-1211 Ground Response Spectrum

(a) The *horizontal* component ground design response spectra of the Safe Shutdown Earthquake (SSE) or the Operating Basis Earthquake (OBE) on sites underlain by rock or by soil may be linearly scaled from Fig. N-1211(a)-1 in proportion to the maximum horizontal ground acceleration specified for the earthquake chosen. [Fig. N-1211(a)-1 corresponds to a

to the maximum horizontal ground acceleration specified for the earthquake chosen. [Fig. N-1211(a)-1 corresponds to a maximum horizontal ground acceleration of 1.0 g and accompanying displacement of 36 in. (914 mm).] The applicable multiplication factors and control points are given in Table N-1211(a)-1. For damping ratios not included in Fig. N-1211(a)-1 or Table N-1211(a)-1, a linear interpolation may be used.

(b) The *vertical* component ground design response spectra of the SSE or the OBE on sites underlain by rock or by soil may be linearly scaled from Fig. N-1211(b)-1 in proportion to the maximum horizontal ground acceleration specified for the earthquake chosen. [Fig. N-1211(b)-1 is based on a maximum horizontal ground acceleration of 1.0 g and accompanying displacement of 36 in. (914 mm).] The applicable multiplication factors and control points are given in Table N-1211(b)-1. For damping ratios not included in Fig. N-1211(b)-1 or Table N-1211(b)-1, a linear interpolation may be used.

N-1212 Time History

N-1212.1 Frequency Content of Time History.

The design ground response spectra used in the earthquake resistance design, such as those illustrated in Figs. N-1211(a)-1 and N-1211(b)-1 for the design of nuclear power plant facilities, are generally based on multi-component time history motions from a number of major earthquakes. There are no single recorded earthquake ground motions which have such uniform frequency distribution. However, it is often necessary to generate a spectrum-consistent time history motion whose response spectrum matches the design response spectrum for a given damping value. The purpose of developing such a spectrum-consistent time history motion is to provide the analyst with an acceptable basis for generating floor (in structure) response spectra and performing time history analysis of systems and components. Several acceptable approaches are presented below.

(a) *Modified Earthquake Records.* An acceptable approach is to modify the components of past earthquake records using spectral raising and suppressing techniques (Refs. 71 and 72).

Spectral raising is accomplished by adding to the original time history a harmonic function at the frequency of interest with a phase angle such that the response spectral value at this frequency will be increased to a desired amount; the time when the maximum vibratory motion occurred will be the same. In this way, the spectral characteristics of the modified time history will be similar to the original earthquake records. Consequently, statistical characteristics of past time history motions can be maintained as discussed in N-1213.

When the time history response spectrum is higher than the design response spectrum at a frequency, spectral suppressing can be carried out by passing the time history through a linearly damped oscillator connected in series with a second damper. This damping arrangement will reduce the response spectral value, locally at the natural frequency of the oscillator, to the desired amount.

This usually requires an iterative procedure. A repetitious application of the raising and suppressing techniques may be used to arrive at a time history motion whose response spectrum is sufficiently close to the design spectrum.

(b) *Synthesized Time History Motions.* Several methods may be used to generate time history motions without the direct use of an actual earthquake record. One method uses power spectral density functions to generate the time history motions. Power spectral density

(PSD) functions may be calculated for the strong motion portion of actual earthquake records by assuming that the strong motion portion is stationary and Gaussian. This (PSD) function may then be used to produce a sample of a pseudo-earthquake ensemble by filtering a white noise record with unit power density through a linear damped system (Ref. 73).

FIG. N-1211(a)-1 HORIZONTAL DESIGN RESPONSE SPECTRA SCALED TO 1 g
HORIZONTAL GROUND ACCELERATION

FIG. N-1211(a)-1 HORIZONTAL DESIGN RESPONSE SPECTRA SCALED TO 1 g HORIZONTAL GROUND
ACCELERATION

FIG. N-1211(b)-1 VERTICAL DESIGN RESPONSE SPECTRA SCALED TO 1 g HORIZONTAL GROUND ACCELERATION

FIG. N-1211(b)-1 VERTICAL DESIGN RESPONSE SPECTRA SCALED TO 1 g HORIZONTAL GROUND ACCELERATION

**TABLE N-1211(a)-1
HORIZONTAL DESIGN RESPONSE SPECTRA
RELATIVE VALUES OF SPECTRUM AMPLIFICATION FACTORS
FOR CONTROL POINTS**

Percent of Critical Damping	Amplification Factors for Control Points			
	Acceleration ^{1,2}			Displacement ^{1,2}
	A (33 Hz)	B (9 Hz)	C (2.5 Hz)	D (0.25 Hz)
0.5	1.0	4.96	5.95	3.20
2.0	1.0	3.54	4.25	2.50
5.0	1.0	2.61	3.13	2.05
7.0	1.0	2.27	2.72	1.88
10.0	1.0	1.90	2.28	1.70

NOTES:

- (1) Maximum ground displacement is taken proportional to maximum ground acceleration and is 36 in. for ground acceleration of 1.0 g.
- (2) Acceleration and displacement amplification factors are taken from recommendations given in Ref. 1 and discussed in Refs. 2 and 3.

TABLE N-1211(a)-1 HORIZONTAL DESIGN RESPONSE SPECTRA RELATIVE VALUES OF SPECTRUM AMPLIFICATION FACTORS FOR CONTROL POINTS

**TABLE N-1211(b)-1
VERTICAL DESIGN RESPONSE SPECTRA
RELATIVE VALUES OF SPECTRUM AMPLIFICATION FACTORS
FOR CONTROL POINTS**

Percent of Critical Damping	Amplification Factors for Control Points			
	Acceleration ^{1,2}			Displacement ^{1,2}
	A (33 Hz)	B (9 Hz)	C (3.5 Hz)	D (0.25 Hz)
0.5	1.0	4.96	5.67	2.13
2.0	1.0	3.54	4.05	1.67
5.0	1.0	2.61	2.98	1.37
7.0	1.0	2.27	2.59	1.25
10.0	1.0	1.90	2.17	1.13

NOTES:

- (1) Maximum ground displacement is taken proportional to maximum ground acceleration and is 36 in. for ground acceleration of 1.0 g.
- (2) Acceleration amplification factors for the vertical design response spectra are equal to those for horizontal design response spectra at a given frequency, whereas displacement amplification factors are $\frac{2}{3}$ those for horizontal design response spectra. These ratios between the amplification factors for the two design response spectra are in agreement with those recommended in Ref. 1 and discussed in Refs. 2 and 3.

TABLE N-1211(b)-1 VERTICAL DESIGN RESPONSE SPECTRA RELATIVE VALUES OF SPECTRUM AMPLIFICATION FACTORS FOR CONTROL POINTS

A second procedure which may be used is to pass Gaussian shot noise through selected filters (Ref. 74). This method may produce acceptable results if used in conjunction with the spectral raising and suppressing techniques described earlier.

Another acceptable procedure involves the superposition of continuous waves with the assumption that earthquake motion is stationary for the strong motion portion of the total time duration. The earthquake is characterized as the product of a normalized stationary process and a scaling factor that establishes the magnitude of the motion and its envelope shape which consists of three distinct parts: the buildup, the flat or stationary portion, and the motion decay. The random process is represented by a finite number of superimposed sine waves with distinct periods and randomly selected phase angles (Ref. 30).

Synthesized time history motions for the three perpendicular directions of an earthquake may not have time phase relationships similar to those of past earthquake records. The procedures of N-1213.1 may be used to check that time phasing is acceptable.

N-1212.2 Duration of Time History

(a) It has been observed (Ref. 51) that the earthquake duration effect on the response spectrum shape is small for periods shorter than 0.5 sec, which is the period range significant for nuclear power plant structures, systems and components.

(b) Although actual long duration earthquakes tend to excite a much wider range of frequencies, this effect is included

in the nuclear power plant design by using the smoothed, envelope type of design response spectra. The use of a design response spectrum in qualifying structures and components dictates that only maximum response amplitudes, be it displacement or stresses, are computed. The duration of ground motions, which is an influence in prolonging large amplitude structural response, may be important when fatigue life of the structures and components is considered. The fatigue effect is discussed in N-1214.

(c) The earthquakes used in producing the recommended response spectra [Figs. N-1211(a)-1 and N-1211(b)-1] occurred almost exclusively in the California area originating along the Circumpacific Belt. They are referred to as type 2 earthquakes in Ref. 51. These type 2 earthquakes are associated with moderate distances from the focus and occur only on firm ground. They last for only a moderate time. The type 2 earthquakes are unlike those referred to as type 3 which occur on soft soil such as the Mexico City earthquakes of July 6, 1964, and which have a much longer duration.

(d) Maximum accelerations of type 2 earthquakes generally occur in the first 10 sec of strong shaking. For instance, the north-south component acceleration recorded at the El Centro earthquake, May 18, 1940, shows that the maximum horizontal ground acceleration of 0.33 g occurs at about 2 sec after the instrument started recording.

(e) Time history analysis is necessary to qualify systems and components which exhibit highly nonlinear characteristics, such as the opening and closing of large gaps between members. Long seismic inputs can waste computation resources. Duration of the artificial time histories should be sufficient to allow the structure enough time to achieve its maximum response. For developing response spectra, the input time history used should be chosen long enough so that the resultant response spectra do not significantly change if the time history is increased. For developing spectrum-consistent time histories, the resultant time history should be long enough so that further increases in its length will not produce significantly different response spectra.

(f) Generally the minimum duration of the strong seismic motion required may be taken as 6 sec for Code components. If this minimum 6 sec strong motion duration is used, then a buildup duration of about 4 sec is recommended to precede the strong motion. The buildup region may be taken as the time duration from where motion is zero to the time where stationarity or strong motion begins. In cases where it is uncertain as to the minimum strong motion duration required to produce maximum structural response, the analysis may be extended to longer strong motion durations such as 10 sec in order to evaluate whether significant response increases occur above those of the 6 sec duration. The method in Ref. 71 may be used when required to include shorter or longer periods of vibratory energy in an artificial time history.

N-1213 Directional and Time Phase Considerations

Three orthogonal components of earthquake excitations are normally considered for nuclear power plant design. Rotational ground motion in the three directions, however, may be neglected. The triaxial input excitations are characterized by the relative magnitudes of

Page 367

the peak accelerations of the three excitations, and the relative values of the response spectra over the frequency range of interest (N-1211). Time histories which are consistent with the design response spectra may be developed through methods discussed in N-1212 and which essentially envelop the design response spectra. Since these artificial time histories may not have time phase relationships similar to those of past earthquake records, the procedures of N-1213.1 may be used to check that time phasing is acceptable.

N-1213.1 Time Phase Relationships.

The peak acceleration of the three orthogonal synthetic time histories generally need not occur at the same time. In order to stimulate natural earthquake occurrences, the correlation of the synthesized time histories may be evaluated by calculating the cross correlation coefficients and the coherence functions (Refs. 4, 5, and 6). The artificially generated time histories are acceptable if both their cross correlation coefficients and their coherence functions are approximately equal to the respective functions for past earthquake records. An absolute value of the correlation coefficient less than 0.16 is acceptable. For the coherence function the numerical values ranging between 0.0 and 0.3 with an average of approximately 0.2 are acceptable.

N-1214 Cyclic Criteria

(a) An acceptable cyclical load basis for fatigue analysis of earthquake loading of equipment and components is 10

equivalent maximum stress cycles per earthquake.

(b) The equivalent maximum stress cycle is defined as the full range including plus or minus seismic load calculated by equivalent static or response spectrum modal analysis techniques.

(c) The total usage factor contribution is based upon the number of earthquakes considered for the component.

N-1220 METHODS OF DYNAMIC ANALYSIS

N-1221 Modeling Techniques for Dynamic Analysis

In the course of preparation.

N-1222 Time History Method

(a) The structural system to be analyzed can be generally classified into two forms, linear and nonlinear. In the linear system the structure is idealized in such a way that the responses and motion retain a linear relation with the applied loads. A nonlinear structural dynamic system may be caused by either a material nonlinearity (i.e., a nonlinear stress-strain relationship of the material), a geometrical nonlinearity (an excessive deformation, a support gap, etc. which significantly changes the geometry of the system), or a mixture of the two.

(b) Dynamic analysis for either a linear or nonlinear system is based on the solution of a set of simultaneous, differential equations of motion with given initial and boundary conditions. Acceptable methods are presented for solution to linear and nonlinear equations in N-1222.

N-1222.1 Linear

(a) The response of a multi-degree-of-freedom linear structural system is described by the differential equation of motion expressed in matrix form:

$$(1) [M] \{\ddot{x}\} + [C] \{\dot{x}\} + [K]x = \{f\}$$

where

M	= mass matrix
C	= matrix of viscous damping coefficients
K	= stiffness matrix for the mass points of the linear elastic structure
f	= force vector and function of time representing external loading at mass points
x	= displacement vector
$\dot{x}$	= velocity vector
$\ddot{x}$	= acceleration vector

In all typical linear matrix formulations, matrices M , C , and K are symmetric.

(b) For a seismic analysis where ground motion is the source of excitation, f in Eq. (1) can be replaced by $[M] \{\ddot{Z}\}$, where $\ddot{Z}$ is the acceleration of ground motion in the same direction of x which is the relative displacement with respect to the ground motion. For systems excited at multiple support locations, further modification of the force vector is necessary (see N-1228).

(c) The differential equation of motion may be solved either analytically or numerically. A rigorous analytical solution of the simultaneous linear differential equations is often impractical and unnecessary. Simplification of the damping matrix may be made to facilitate computations.

(d) For example, in the special case of proportional damping (i.e., when the damping matrix is reduced to a linear combination of the mass and stiffness matrices), the classical method of modal analysis may be applied since Eq. (1) can be decoupled.

(e) See N-1230 for acceptable treatments of damping. A numerical solution using step-by-step integration method may be applied to a set of coupled as well as uncoupled differential equations. The direct integration method does not require the process of uncoupling modes; therefore, no calculation of natural frequencies and mode shapes is necessary. The direct integration method permits the handling of proportional damping where this treatment is required.

N-1222.1.1 Method of Modal Superposition (Ref. 8)

N-1222.1.1.1 Modal Analysis.

The method of modal analysis usually assumes that a modal matrix be defined such that

$$[\phi]^T [M] [\phi] = [I]$$

$$[\phi]^T [K] [\phi] = [\omega^2] \quad (2)$$

$$[\phi]^T [C] [\phi] = [2\xi\omega]$$

(2) where the right-hand sides are diagonal matrices, ϕ is the modal matrix, ω is the natural frequency of the structure, and ξ is the modal fraction of critical damping. This formation uses damping matrices that are proportional.

Let $\{\eta\}$ be the normal coordinates such that the displacement $\{x\}$ can be defined by the transformation

$$(3) \{x\} = [\phi] \{\eta\}$$

Equation (1) can be written by means of this transformation as

$$(4) \{\ddot{\eta}\} + 2\xi\omega \{\dot{\eta}\} + \omega^2 \{\eta\} = [\phi]^T \{f\}$$

which represents a decoupled system of individual modal equations. Response in each mode may be obtained by solving the differential equations individually for the corresponding mode. The total response of the structure is therefore the result of combining the responses of all its component modes.

The equations of motion for a linear system may be uncoupled by means of a transformation to a system of normal coordinates provided that the damping matrix C is a linear combination of M and K matrices.

N-1222.1.1.2 Complex Frequency Response Method.

As an alternative approach to the method of modal analysis described above, the complex frequency response method may be used to determine dynamic response of the system represented by Eq. (1).

The complex frequency response method requires that the complex frequency responses of the system be determined first and the seismic excitations be transformed into its frequency domain. The time histories of the response may then be found by inverting the response transforms.

Corresponding to every normal coordinate η_r of Eq. (4), a pair of Fourier transforms may be found:

$$G_r(\Omega) = \int_{-\infty}^{\infty} \eta_r(t) e^{-i\Omega t} dt \quad (5)$$

$$Q_r(\Omega) = \int_{-\infty}^{\infty} f_r(t) e^{-i\Omega t} dt$$

(5)

where

$$f_r(t) = \{\phi_r\}^T \{f(t)\}$$

The Fourier transforms of the excitation and response are related according to

$$(6) G_r(\Omega) = H_r(\Omega) Q_r(\Omega)$$

and

$$H_r(\Omega) = \frac{1}{1 - (\Omega/\Omega_r)^2 + i2\xi(\Omega/\Omega_r)} \quad (7)$$

(7)

The r th mode response is given by evaluating the Fourier integral:

$$\eta_r(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} H_r(\Omega) Q_r(\Omega) e^{i\Omega t} d\Omega \quad (8)$$

(8)

and the time history response of the system in the physical coordinate is given by

$$\{x(t)\} = \sum_{r=1}^{\eta} \{\phi_r\} \eta_r(t) \quad (9)$$

(9)

Standard fast Fourier transform techniques are available for expedient evaluation of $Q_r(\Omega)$ and $\eta_r(t)$ of Eqs. (6) and (8), respectively (Ref. 9).

Page 369

N-1222.1.2 Method of Direct Integration

(a) This is a numerical method directly applied to the solution of the differential equations of motion of linear structural system, Eq. (1), in a step-by-step manner. No uncoupling procedure is necessary to compute the responses. The damping matrix need not be proportional.

(b) There are many acceptable schemes available for numerical integration of the equations of motion such as Newmark β -method (Ref. 10), Houbolt method (Ref. 11), and Wilson θ -method (Ref. 12).

(c) Using the matrix formulation by Chan, Cox, and Benfield (Ref. 13) and Newmark β -method, Eq. (1) may be transformed into a finite difference equation in recurrence form involving displacement:

$$[D] \{x_{n+1}\} = [B] \{x_n\} - [F] \{x_{n-1}\} + \beta h^2$$

$$\left\{ f_{n+1} + \left(\frac{1}{\beta} - 2 \right) f_n + f_{n-1} \right\} \quad (10)$$

(10)

where

$[D]$	$= [M] + (h/2)[C] + \beta h^2[K]$
$[B]$	$= 2[M] - (1 - 2\beta)h^2[K]$
$[F]$	$= [M] - (h/2)[C] + \beta h^2[K]$
h	= length of the time interval used in the direct integration procedure
β	= parameter of Newmark β -method in reflecting the type of acceleration function assumed between two time stations and numerical stability of the procedure
n	= the number of time intervals lapsed

(d) The dynamic responses of a structure at any instant of time may be calculated from the time history of excitations and the previous structural responses.

(e) The direction integration method has the advantage of simplicity in computation and elimination of the eigenvalue problem. This method may also be extended to deal with the nonlinear problems.

N-1222.2 Nonlinear

(a) The linear time history analysis discussed in N-1222.1 is based on the assumptions that external forces are independent of the displacement and velocity, the stress-strain relationship is linear, and the strain-displacement relationship is linear. Many problems of practical consequences exist for which these assumptions are not valid. Some acceptable numerical methods to analyze such nonlinear problems are discussed below.

(b) The following nonlinearities may be introduced into the system:

- (1) material nonlinearities (plasticity);
- (2) geometric nonlinearities (large displacement);
- (3) combination of material and geometric nonlinearities (impact and friction).

(c) The differential equation of motion for nonlinear problems is

$$(11) [M_p]\{U''\} + [C_p]\{U'\} + [K_p]\{U\} = \{P_p\}$$

where

M_t	= time-dependent mass
C_t	= damping
K_t	= stiffness matrices
U	= displacement
U'	= velocity
U''	= acceleration
P_t	= force arrays

The left-hand side of Eq. (11) may be made linear by introducing

$$\begin{aligned}
 [M_t] &= [M] + [M_{nl}] \\
 [C_t] &= [C] + [C_{nl}] \\
 [K_t] &= [K] + [K_{nl}]
 \end{aligned}
 \tag{12}$$

(12)

where

M	= time-independent mass
C	= proportional damping
K	= stiffness matrices
M_{nl}	= time-dependent mass
C_{nl}	= damping
K_{nl}	= stiffness matrices

As an example, the compressible fluid flow in a pipe or a moving mass acting on a structure contributes to $[M_{nl}]$ and the closing and opening of gaps contribute to $[C_{nl}]$ and $[K_{nl}]$. Substituting Eq. (12) into Eq. (1) yields

$$(13) \quad [M] \{U''\} + [C] \{U'\} + [K] \{U\} = \{F\}$$

where

$$\{F\} = \{P_t\} - [M_n]\{U'''\} - [C_n]\{U''\} - [K_n]\{U\}$$

Time history methods to solve Eq. (11) or (13) fall into two major categories: (1) mode superposition, and (2) direct integration.

N-1222.2.1 Mode Superposition

(a) The use of normal modes for linear time history method is discussed in N-1222.1. Mode superposition techniques may also be used for the nonlinear problems

Page 370

(Refs. 14, 15, and 16). A problem of a pendulum having a large amplitude is discussed in Ref. 14. Reference 15 presents an analysis of a structure including the following nonlinear characteristics: variable-stiffness elements, contact (compression only) elements, time-varying boundary conditions, and nonmodal and nonlinear damping elements. A ring problem involving large geometric nonlinearities and plastic strains is discussed in Ref. 16.

(b) Let $\{\phi_i\}$ and $\{\omega_i\}$ be the i th orthonormal eigenvector and natural frequency, respectively:

$$(14) [M] \{U'''\} + [K] \{U\} = 0$$

A transformation

$$(15) \{U\} = [\phi] \{q\}$$

is introduced in Eq. (13). The resulting uncoupled equation is as follows:

$$(16) [I] \{q'''\} + [2\xi_j\omega_j] \{q'\} + [\omega_j^2] \{q\} = \{p\}$$

where

I	= identity matrix
	$= [\phi]^T [M] [\phi]$
ϕ	= set of significant eigenvectors
q	= generalized displacement vector
ξ_j	= j th modal damping ratio
ω_j	= j th natural frequency
P	= generalized force
	$= [\phi]^T \{F\}$

(c) Eq. (16) may be solved by either explicit numerical integration schemes such as the fourth order Runge-Kutta method (Ref. 17), Hamming's predictor-corrector method (Ref. 17), or by the analytical integration scheme (Ref. 14). These numerical methods are conditionally stable and available as library programs equipped with an automatic time step adjustment feature. These methods provide a stable solution if the integration time step is appreciably smaller than the smallest period associated with Eq. (16). In the analytical integration method, the force vector F is approximated over the time step Δt . This allows for Duhamel integral type solutions for Eq. (16).

(d) The generalized forces in Eq. (16) are updated at each time increment. If the initial stiffness matrix has a relatively large bandwidth and a large number of eigenvectors are not required for the analysis, it is likely that the mode superposition approach will be quite economical as compared with the direct integration procedures discussed in N-1222.2.2. In cases where the applied load distribution is extremely complex or its time variation contains significant high frequency components, or both, it is necessary to include many modes to obtain adequate accuracy by mode superposition. In these cases the direct integration procedure may be more efficient. This procedure is discussed in N-1222.2.2.

N-1222.2.2 Direct Integration.

Direct numerical integration methods can be applied to Eq. (11) or (13). When applied to Eq. (11), the calculation

of time-dependent matrices is necessary at each integration time step. When applied to Eq. (13), the time-independent matrices may be calculated once at the beginning of the numerical solution and the time-dependent force array is calculated at each time step. These methods are classified into two groups: explicit schemes and implicit schemes. The explicit schemes are hampered by both numerical instability and convergence problems while the implicit schemes suffer only from convergence problems. These schemes are discussed in N-1222.2.2.1 and N-1222.2.2.2.

N-1222.2.2.1 Explicit Schemes.

These schemes convert the differential equations of motion to a set of linear algebraic equations with unknown state variables (at the present time) which are independent of one another. Acceptable explicit schemes include: Runge-Kutta method (Ref. 17), predictor-corrector method (Ref. 17), Nordsieck integration method (Ref. 18), and central difference method (Ref. 19).

As the above methods are conditionally stable, they have a disadvantage of requiring small time step sizes. The first three methods can be made to operate with the variable time step, while the fourth one is a constant time-step procedure. Garnet and Armen (Ref. 20) demonstrate a one dimensional wave propagation problem solution with the aid of a predictor-corrector method, i.e., the modified Adams method. In Ref. 21 the Nordsieck integration scheme is demonstrated to solve nonlinear vibration problems in reactor components. Wu and Witmer (Ref. 22) analyzed the problem of large transient elastic-plastic deformation of structures using the central difference method.

N-1222.2.2.2 Implicit Schemes.

These schemes convert the differential equations of motion to a set of linear simultaneous algebraic equations and require a matrix inversion to step the solution forward. Acceptable implicit schemes include: Newmark's generalized acceleration method, Wilson's θ method, Nastran's integration method, and Houbolt's method.

(a) *Acceptable implicit schemes:*

(1) *Newmark's Generalized Acceleration Method* (Refs. 10 and 23). The nodal point velocities and displacements are given by the following equations:

$$(17) \{U'_{n+1}\} = \{U'_n\} + (1 - \gamma)(\Delta t)\{U''_R\} + \gamma(\Delta t) \{U''_{n+1}\}$$

and

$$(18) \{U_{n+1}\} = \{U_n\} + (\Delta t) \{U'_n\} + (1/2 - \beta)(\Delta t)^2\{U''_n\} + \beta(\Delta t)^2 \{U''_{n+1}\}$$

Equations (17) and (18) are substituted in Eq. (13), which is expressed at the present time point $(n + 1)$. This gives the following:

$$\begin{aligned}
& \left[[M] + \gamma(\Delta t)[C] + \beta(\Delta t)^2[K] \right] \{U''_{n+1}\} \\
& = \{F_{n+1}\} - \left[(1 - \gamma)(\Delta t)[C] \right. \\
& \quad \left. + (1/2 - \beta)(\Delta t)^2[K] \right] \{U''_R\} \\
& \quad - \left[[C] + (\Delta t)[K] \right] \{U'_n\} - [K] \{U_n\} \quad (19)
\end{aligned}$$

(19)

This set of algebraic simultaneous equations in the unknown accelerations is solved and used with Eqs. (17) and (18) to obtain the velocity and displacement at the present time. The parameter γ in Eq. (19) is a damping parameter. Artificial positive damping is introduced if $\gamma > 0.5$ and artificial negative damping if $\gamma < 0.5$. For linear problems, the method is unconditionally stable if $\beta > (2\gamma + 1)^2 / 16$ (Ref. 12). For $\gamma = 1/2$, $\beta > 1/4$ gives unconditional stability. For systems with nonlinearities or nonproportional damping or both, there is no analytical expression available for unconditional stability. So to provide a margin of stability for these systems $\beta > 1/4$ is considered for $\gamma = 1/2$. The value of γ slightly larger than 0.5 damp out the highest (and least important) modes while preserving the lower ones. The Newmark method for $\gamma = 1/2$ (no numerical damping) and $\beta = 1/6$ (linear acceleration) is conditionally stable. The Wilson modified method (to make it unconditionally stable) is discussed next.

(2) Wilson's θ Method (Ref. 12). To obtain the solution at the present time $(n + 1)$, this method assumes that the acceleration varies linearly over the time interval $\tau = \theta \Delta t$, where $\theta > 1.0$. With the aid of Eq. (19), $\beta = 1/6$ and $\gamma = 1/2$, solution at time point $(n + \theta)$ is obtained. Then the acceleration, velocity, and displacement at the time point $n + 1$ are given by the following expressions:

$$\{U''_{n+1}\} = (1 - 1/\theta)\{U''_n\} + (1/\theta)\{U''_{n+\theta}\}$$

$$\{U'_{n+1}\} = \{U'_n\} + \frac{\Delta t}{2} \{ (U''_n + U''_{n+1}) \}$$

$$\begin{aligned} \{U_{n+1}\} = \{U_n\} + \Delta t \{U'_n\} + \frac{\Delta t^2}{6} (U''_{n+1} \\ + 2U''_n) \end{aligned} \quad (20)$$

(20)

The last two equations are obtained from Eq. (18) with the value of β and γ specified above. This method is unconditionally stable for $\theta > 1.37$ (Ref. 12); for $\theta = 1.4$, the numerical damping is less than 1% provided 22 steps are taken within the natural period of the mode of interest (Ref. 25).

(3) *Nastran's Integration Method* (Ref. 26). In this method the acceleration and velocity are expressed in central finite difference form. They are expressed as follows:

$$\{U''_n\} = \frac{\{U_{n+1}\} - \{2U_n\} + \{U_{n-1}\}}{(\Delta t)^2}$$

$$\{U'_n\} = \frac{\{U_{n+1}\} - \{U_{n-1}\}}{2(\Delta t)} \quad (21)$$

(21)

The displacement and the forcing function are expressed as the weighted average of the corresponding magnitudes at the three successive time points $n-1, n, n+1$. Substitution of these expressions in Eq. (13) expressed at time point n gives:

$$\begin{aligned}
& \left[\frac{1}{(\Delta t)^2} [M] + \frac{1}{2(\Delta t)} [C] + \frac{1}{3} [K] \right] \{ U_{n+1} \} \\
&= \frac{1}{3} \{ F_{n+1} + F_n + F_{n-1} \} + \left[\frac{2}{(\Delta t)^2} [M] - \frac{1}{3} [K] \right] \{ U_n \} \\
&+ \left[-\frac{1}{(\Delta t)^2} [M] + \frac{1}{2(\Delta t)} [C] - \frac{1}{3} [K] \right] \{ U_{n-1} \} \quad (22)
\end{aligned}$$

(22)

This set of algebraic simultaneous equations in the unknown displacements is solved and used to find velocity and acceleration.

This scheme is a special form of the Newmark method, Eq. (18) for $\beta = 1/3$ and $\gamma = 1/2$ (Ref. 13). The value $\beta = 1/3$ provided some margin of stability

Page 372

and for $\gamma = 1/2$ the artificial damping is zero. Note that the load vector F is averaged over three adjacent time steps in the same manner that K is averaged. This is done in order to provide statically correct solutions for massless degrees of freedom.

(4) *Houbolt's Method* (Ref. 11). In this method a third-order interpolating polynomial which fits the known displacements at the three previous time points and the unknown displacement at the present time point is formulated. The expressions for acceleration and velocity are given as follows:

$$\begin{aligned}
\{U''_{n+1}\} &= \frac{1}{(\Delta t)^2} [2\{U_{n+1}\} - 5\{U_n\} \\
&\quad + 4\{U_{n-1}\} - \{U_{n-2}\}] \\
\{U'_{n+1}\} &= \frac{1}{6(\Delta t)} [11\{U_{n+1}\} - 18\{U_n\} \\
&\quad + 9\{U_{n-1}\} - 2\{U_{n-2}\}] \quad (23)
\end{aligned}$$

(23)

The Eqs. (23) are substituted in Eq. (13) which is expressed at the present time point $n + 1$. This gives:

$$\begin{aligned}
& \left[\frac{2}{\Delta t^2} \left(\frac{11}{6\Delta t} \right) [C] + [K] \right] \{U_{n+1}\} \\
& = \{F_{n+1}\} + \left[\frac{5}{\Delta t^2} [M] + \frac{3}{\Delta t} [C] \right] \{U_n\} \\
& \quad - \left[\frac{4}{\Delta t^2} [M] + \frac{3}{2\Delta t} [C] \right] \{U_{n-1}\} \\
& \quad + \left[\frac{1}{\Delta t^2} [M] + \frac{1}{3\Delta t} [C] \right] \{U_{n-2}\}
\end{aligned}$$

This set of algebraic simultaneous equations in the unknown displacements is solved and used to find velocity and acceleration.

This method is unconditionally stable for linear problems and introduced artificial damping (the amount of such damping increases with the ratio of time step to natural period of the system). The artificial damping is less than 1% provided 50 time steps are taken within the natural period of the mode of interest (Ref. 12). Thus, the Houbolt method effectively removes higher mode response from the system.

(b) *Approximation of Load Vectors.* All four direct integration methods discussed in the previous section require that the forces at the time point $n+1$ be known in order to calculate the displacements at that time. These loads, because of the presence of the nonlinear terms, are a function of the displacements which are to be calculated. So, it is not possible to evaluate these terms exactly. These forces may be approximated with the aid of the first-order Taylor series expansion about the motion at time point n as follows:

$$\{F(t, U)_{n+1}\} = \{F(t, U)_n\} + \frac{\delta}{\delta t} \{F(t, U)_n\} (\Delta t)$$

$$= 2\{F(t, U)_n\} - \{F(t, U)_{n-1}\}$$

This expression has an inherent error of order $(\Delta t)^2$ which is the same as the Houbolt and Nastran method (Ref. 27). This expression corresponds to a linear extrapolation of the loads at the two previous time increments which is equivalent to a numerical differentiation. This introduces round off error (noise) which will set a low bound on the integration time step.

(c) *Convergence.* For nonlinear systems, the following two steps are recommended to ensure convergence of the solution to the proper value.

(1) Iterative schemes, based on the residual force array derived from the equation of motion at the present time point $n + 1$ may be used to obtain convergence. This residual, obtained by transferring all the terms in Eq. (13) to the right-hand side, is a measure of how well the dynamic equilibrium is satisfied at the present time point $n + 1$. The time-dependent matrices and force arrays, in Eqs. (11) and (13), respectively, are modified based on the calculated solution at time point $n + 1$ and the iterative scheme is continued until the dynamic equilibrium is satisfied to a prescribed tolerance. References 25, 28, and 29 discuss this approach to improve efficiency in nonlinear solutions.

(2) Successive computation of the time history, employing successively smaller values of the integration time step, may also be used to ascertain convergence.

In the wave propagation problems, the response may contain the spurious oscillations (Refs. 20 and 25), which are due to the finite element discretization, and are not eliminated by reducing the time step Δt . These oscillations may often be reduced by employing more uniform element size.

(d) *General Remarks.* No best choice of numerical method has been identified for nonlinear problems. Discussions which are helpful to indicate the advantages and limitations of these previously discussed methods are contained in Refs. 13, 20, 22, 23, and 27.

Experience obtained from the solution of actual problems is the most reliable indicator of which of the

Page 373

different integration schemes is superior for a particular problem. Experience and checks of methods adopted for a similar type of physical problem where a correct solution is available is recommended to establish validity for a particular nonlinear method.

N-1222.3 Time History Broadening.

To account for the effect of possible frequency variation of the structure, the same time history data may be used with at least three different scaled time intervals: Δt (the reference interval) and $(1 \pm \Delta f/f_j)\Delta t$, for the analysis of equipment, where f_j is the fundamental structural frequency and Δf_j is a parameter defining the frequency variation due to uncertainties. This variation of the time scale interval has a similar effect to widening the spectral peak when generating the smoothed response spectrum. If one of the equipment frequencies f_e is within the range $f_j \pm \Delta f_j$, it is recommended that the time history also be used with additional scaled time intervals of $[1 \pm (f_e - f_j)/f_j]\Delta t$.

N-1223 Response Spectrum Method

N-1223.1 Modal Combination.

In the response spectrum method, the peak values of particular responses of interest (displacement, acceleration, shear, moment, etc.) are determined for each mode. The total response may be obtained by combining the peak modal responses by the square root of sum of squares (SRSS) method. Mathematically this is expressed as follows:

$$R = \pm \left[\sum_{k=1}^n R_k^2 \right]^{1/2} \quad (24)$$

(24)

where

R	= the total response of interest (strain, displacement, stress, moment, shear, etc.) based on the SRSS method of combining the individual peak modal responses
R_k	= the peak response of interest due to the k th mode
n	= the number of significant modes

The above method may be used to determine the particular response for all significant modes regardless of frequency spacing.

N-1223.2 Combination of Effects Due to Triaxial Excitation

(a) In the response spectrum method of analysis, the natural frequencies, mode shapes, and the load for each mode are first determined. The load for each mode for unit generalized response is the product of the stress matrix, the mode shapes, and the mode participation factors. When this product is multiplied by the generalized response determined from the spectrum curves, the load for each natural mode results.

(b) The following assumptions may be used in combining the loads of each natural mode and for each direction.

(1) The peak responses of the different modes due to any one excitation do not occur at the same time.

(2) The peak generalized responses due to the three different earthquake excitations for the same mode do not occur at the same time.

(3) The peak stresses due to different modes and due to different excitations generally do not occur at the same location on the structure nor at the same angular orientation.

(c) These assumptions are consistent with the use of the SRSS method to compute the resultant responses. It is necessary to use the SRSS method only on scalar components because the SRSS of components orthogonal to each other results in magnitudes equivalent to vector sums thus implying simultaneous occurrence.

(d) The following general procedure should be used to combine the seismic responses due to triaxial excitation:

$$R_{ij} = \pm \left[\sum_{k=1}^3 R_{ijk}^2 \right]^{1/2} \quad (25)$$

(25)

where

R_{ijk}

= maximum, co-directional seismic response of interest (strain, displacement, stress, moment, shear, etc.) associated with coordinates i and j due to earthquake excitation in the k th direction

R_{ij}

= seismic response of interest for design (strain, displacement, stress, moment, shear, etc.) obtained by the SRSS rule to account for the nonsimultaneous occurrences of R_{ijk}

N-1224 Component or Equipment Testing

In the course of preparation.

N-1225 Simplified Dynamic Analysis

N-1225.1 Seismic Load Coefficient Method for Piping System Analysis

N-1225.1.1 Simplified Seismic Load Coefficient Method Using Floor or Amplified Response Spectra as the Seismic Design Basis Input

(a) Piping System Loads. A simplified seismic load coefficient method for earthquake resistant design for

Page 374

equivalent seismic inertia induced resultant piping stresses, displacements, loads, and support reaction loads may be used to describe the earthquake input with a format as follows:

$$(26) F_{phi} = K_{hi} S_{ami} W$$

$$(27) F_{pv} = K_v S_{ami} W$$

where

F_{phi}

= equivalent static inertia force applied to the piping and piping components in the i th horizontal direction as defined in N-1225.2

F_{pv}

= equivalent static inertia force applied to the piping and piping components in the vertical direction as defined in N-1225.2

K_{hi}

= the load coefficient applied to the piping and piping

components in the i th horizontal direction. The value of K_{hi} shall be determined as follows:

For Soil Sites: $V_s < 3500$ ft/sec

$$K_{hi} = 1.0; l_{hi} < 3.5 l_v$$

$$K_{hi} = 0.65; 3.5 l_v \leq l_{hi} \leq 5.0 l_v =$$

$$K_{hi} = 0.4; l_{hi} < 5.0 l_v$$

For Rock Sites: $V_s > 3500$ ft/sec

$$K_{hi} = 1.0; l_{hi} < 2.5 l_v$$

$$K_{hi} = 0.6; 2.5 l_v \leq l_{hi} \leq 4.0 l_v$$

$$K_{hi} = 0.4; l_{hi} < 4.0 l_v$$

Piping systems with l_{hi} in more than one of the categories listed above shall use the highest K_{hi} value applied to two lateral support spans on either side of the span requiring the highest K_{hi} value.

K_v = the load coefficient applied to the piping in the vertical direction. The value of K_v shall be determined as follows:

For Soil Sites: $V_s < 3500$ ft/sec

$$K_v = .75; l_{hi} < 4.0 l_v$$

$$K_v = 1.0; l_{hi} > 4.0 l_v$$

For rock Sites: $V_s > 3500$ ft/sec

$$K_v = 1.0$$

Piping systems with l_{hi} in more than one of these categories listed above shall use the highest K_v values applied to two lateral support spans on either side of the span requiring the highest K_v value.

S_{ami} = peak acceleration of applicable amplified or floor response spectra in the i th direction (in g's)

l_{hi} = span in the i th direction between lateral supports measured along the axis of the pipe. Lateral supports added to the piping system next to large inline components whose weights equal or exceed the weight of the pipe between nominal dead weight supports contained in Table NF-3611.1, such as valves, strainers, etc., do not need to be considered in the

l_v	determination of l_{hi} value = deadweight vertical support span from Table NF-3611.1 for the nominal pipe size for the piping system under consideration
V_s	= building foundation media shear wave velocity
W	= the total piping dead load (weight) which exists during the postulated seismic event. This includes piping weight, water weight and insulation. The units of the term W must be consistent with those of the term F_{phi} and F_{pv} above. When the piping system under consideration contains more than one pipe size K_{hi} and K_v factors shall be separately determined for and applied to each nominal pipe size in the piping system. In addition, if the K_{hi} and K_v values change as a result of a pipe size change, the highest K_{hi} , K_v values at the point of piping size change shall be applied to the first two lateral support spans at the point piping size change having the lower K_{hi} K_v values.

(b) *Special Considerations for Support Reactions.* In using this method to determine piping supports loads for seismic events, the specification of a minimum lateral and vertical support design load is required. This minimum design load is a function of pipe size and shall be determined as follows:

$$R_{Lmin} = (MSLF)(w') \left[\sum_{i=1}^2 (S_{ami})^2 \right]^{1/2} \quad (28)$$

$$R_{Amin} = (MSLF)(w') \left[\sum_{i=1}^2 (S_{ami})^2 \right]^{1/2} \quad (29)$$

(28 - 29)

where

The S_{ami} values are the peak accelerations of the applicable amplified or floor response spectra in each of two orthogonal horizontal directions (units are g's)

$$R_{vmin} = (MSLF)(w')(S_{ami})$$

where:

S_{ami} is the peak acceleration of the applicable amplified or floor response spectra in the vertical direction.

The remaining parameters are defined as follows:

$MSLF$	= the Minimum Support Load Factor as defined in Table N-1225.1.1(b)-1 (MSLF has the units of ft)
--------	--

Page 375

R_{Lmin}	= Minimum Lateral Seismic Support Design Support Load (R
------------	---

R_{Amin}	L_{min} has the units of lb ρ) = Minimum Axial Seismic Support Design Load for these axial supports not in the vertical direction. For axial supports in the vertical direction the minimum support design load shall be determined as R_{Vmin} (R_{Amin} has units of lb ρ)
R_{Vmin}	= Minimum Vertical Seismic Support Design Load (R_{Vmin} has the units of lb ρ)
w'	= the total piping dead load per unit length of the piping which exists during a seismic event. This includes piping weight, water weight, insulation weight, etc. (w' has the units of lb ρ /ft).

**TABLE N-1225.1.1(b)-1 MINIMUM
SUPPORT LOAD FACTOR**

Nominal Pipe Size [ϕ], NPS	MSLF (ft)
$\phi \leq 2$	8.5
$2 < \phi \leq 4$	8.0
$4 < \phi \leq 6$	7.5

TABLE N-1225.1.1(b)-1 MINIMUM SUPPORT LOAD FACTOR

In instances where Seismic Support Design Loads determined using the methodology of N-1225.1(a) are less than R_{Lmin} , R_{Amin} or R_{Vmin} the support design load shall be specified as R_{Lmin} , R_{Amin} or R_{Vmin} as determined in this subarticle.

(c) *Inline Component Extended Structures.* The seismic applied accelerations at the center of gravity (cg) of inline component extended structures may be determined as follows:

$$av_h = \left[\sum_{i=1}^2 (0.9S_{ami})^2 \right]^{1/2} \quad (30)$$

(30)

when

The S_{ami} values are the peak accelerations of the applicable amplified or floor response spectra in each of two orthogonal horizontal directions.

$$av_v = 1.2 S_{ami} \quad (31)$$

(31)

when:

The S_{ami} value is the peak of the applicable amplified floor response spectra in the vertical direction.

The remaining parameters are defined as follows:

av_h	= the total acceleration applied to the inline component extended structure center of gravity (cg) in the horizontal direction
av_v	= the acceleration applied to the inline component extended structure center of gravity (cg) in the vertical direction

The application of the equations (30) and (31) to determine Inline Component Extended Structures applied accelerations shall be limited to $W_v h^2 / w'$ values less than or equal to 185,000 ft-in², when:

W_v	= weight of the inline component extended structure considered at it's center of gravity (cg) location (lb _p)
h	= height from the pipe centerline to inline component extended structure center of gravity (cg) (inches)
w'	= is as previously defined

For inline components when the extended structure vertical (axial) axis does not correspond to global vertical axis, the method is still applicable but care must be taken to insure that S_{ami} and equations (30) and (31), when applied, correspond to the inline component local vertical (axial) and lateral axes.

correspond to the inline component local vertical (axial) and lateral axes.

This method for inline piping component extended structure acceleration prediction is applicable only to those inline piping components where the extended structure of the inline component has a frequency greater than 20 hz. The inline piping component frequency determination can be made by analysis, test, or judgement, and when making this frequency determination, the inline piping component body shall be or shall be assumed to be rigidly constrained.

(d) This method is limited to NPS 6 and smaller.

N-1225.2 Analysis Using the Seismic Load Coefficient Method

When seismic forces F_{phi} or F_v are determined from the equations of N-1225.1.1(a), they shall be assumed as statically applied inertia loads acting along three orthogonal axes defined relative to the piping system with one of these axes being in the vertical direction. The piping system seismic analysis shall be performed independently for each direction of excitation with the loads applied in the same sense. Resultant internal forces, moments or stresses in the piping products and piping supports determined from seismic loads in the three directions, may be combined by the square root sum of squares basis and will be considered as having both a (+) and (-) sign. In developing the piping system analytical models for this method, consideration shall be given to appropriately simulating the effects of localized concentrated mass effects assumed from such

Page 376

piping products as flanges, inline instrumentation, valves (including extended structures), etc.

The seismic forces defined by the equations of N-1225.1.1(a) consider only inertia effects. They do not include the effects of relative or differential motions between piping supports and motions of equipment to which the piping is attached. These effects are typically referred to as seismic anchor motions.

For this piping analysis method the piping supports may be assumed to be zero displacement points in the direction of restraint.

N-1226 Floor Spectrum Generation

(a) Nuclear facility structures are approximated by mathematical models to permit analysis of responses due to earthquake motions. Considering the large number of degrees of freedom that would be necessary and the possible ill-conditioning of the resulting stiffness matrix if the complete plant were idealized as a single mathematical model, the plant is usually separated into several separate subsystems for analysis purposes. There will usually be one or more primary structural models which support one or more secondary systems. Also, different models of the same structure may be required for different purposes. Specifically, the dynamic model used to generate the seismic excitation data for subsequent, separate analyses of the secondary systems may not be suitable for the detailed, localized stress analysis of the primary structure.

(b) Most equipment will have negligible interaction effects on the primary structure as in the case of equipment with relatively small mass and high frequency, and will only need to be included in the mass distribution of the primary system model. There are, however, major equipment systems, such as a reactor coolant system, whose stiffness, mass, and resulting frequency range should be considered for representation in the building model to account for possible dynamic interaction effects. Some guidelines for determining the extent of interaction are given in Refs. 31 through 33.

(c) Equipment may be analyzed by combining the complete equipment model with the support structure model and applying the proper excitation to the base of the support structure. In this method no separate equipment support excitations need be generated because the equipment will be excited directly through the structure (Ref. 34).

(d) For most equipment a separate analysis of the secondary system may be performed using output from the building analysis. If building to equipment interaction is significant, then the equipment should be included in the mathematical model of the structure. The representation of the equipment which is included in the building model should be adequate to consider major interaction effects, but need not be as detailed as the mathematical model used in a separate analysis of the equipment.

(e) For equipment which is not analyzed as part of the building structural model, the response may be obtained by separate analysis using floor response spectra curves, time history excitations, or an appropriately defined power spectral

density function at the support locations of the equipment in the structure.

N-1226.1 Response Spectra

(a) Both horizontal and vertical response spectra may be computed from the time history motions of the structure at the various floors or other equipment support locations of interest (Ref. 35). The spectrum ordinates should be computed at sufficient frequency intervals to produce complete and accurate response spectra. Spectrum peaks would normally be expected to occur at the frequencies of the peaks on the ground motion spectrum and at the natural frequencies of the supporting structures. In cases involving equipment mounted on equipment, the frequencies of all supporting structures should be included.

(b) Table N-1226-1 provides some systematic methods which may be used for choosing spectrum frequencies. Another acceptable method is to choose a set of frequencies such that each frequency is within 10% of the previous one and then add the natural frequencies of the supporting structures to the set.

(c) A more simplified acceptable method for constructing floor response spectra from the ground spectrum is given in Refs. 36 and 37.

N-1226.2 Spectral Peaks.

Studies (Refs. 38 and 39) have shown that, in general, the calculation of response of a piece of equipment having a frequency equal to a frequency of the supporting structure will be conservative if the spectrum at the equipment support is generated using a model of the supporting structure which does not include the equipment. This is because the exact resonance of an uncoupled analysis is not possible in the coupled case where the resonant frequencies tend to shift away from each other when the models are coupled. Further, it has been shown in Ref. 39 that undamped peak amplification for singly supported equipment structures cannot exceed a maximum $\sqrt{J/m}$, where J is the modal mass for each mode of the primary structure and m is the mass of the supported subsystem. Since this limit is a function of the mass of the particular subsystem, the peak response

Page 377

may be calculated on a case-by-case basis. This rule is recommended only for relatively simple systems.

TABLE N-1226-1
SUGGESTED FREQUENCIES, Hz, FOR CALCULATION OF GROUND AND FLOOR RESPONSE SPECTRA

Ground Spectra ¹		Floor Spectra ²	
Frequency Range	Increment, Hz	Frequency Range	Increment, Hz
0.5–3.0	0.10	0.5–1.6	0.10
3.0–3.6	0.15	1.6–2.8	0.20
3.6–5.0	0.20	2.8–4.0	0.30
5.0–8.0	0.25	4.0–9.0	0.50
8.0–15.0	0.50	9.0–16.0	1.0
15.0–18.0	1.0	16.0–22.0	2.0
18.0–22.0	2.0	22.0–34.0	3.0
22.0–34.0	3.0		

NOTES:

- (1) Calculate response at all frequencies within the ranges shown, at the corresponding increments (results in 72 frequencies).
- (2) Calculate response at all frequencies within the ranges shown, at the corresponding increments (results in 46 frequencies); also calculate response at all natural frequencies of the supporting structures with the overall range.

TABLE N-1226-1 SUGGESTED FREQUENCIES, Hz, FOR CALCULATION OF GROUND AND FLOOR RESPONSE SPECTRA

N-1226.3 Spectrum Peak Broadening

(a) To account for the effect on structural frequency variation of the possible uncertainties in the material properties of the structure and soil, and the approximations in the modeling techniques used in seismic analysis, the initially

computed floor response spectra are usually smoothed, and peaks associated with the structural frequencies are widened. A recommended method of determining the amount of peak widening, associated with the structural frequency, is described below.

(b) Let f_j be the j th mode structural frequency which is determined from the structure model. The variation in the structural frequency is determined by evaluating the individual frequency variation due to the variation in each parameter that is of significant effect, such as the soil modulus, material density, etc. The total frequency variation $\pm \Delta f_j$ is then determined by taking the SRSS of a minimum variation of $0.05f_j$ plus the individual frequency variation $(\Delta f_j)_n$ that is:

$$\Delta f_j = \sqrt{(0.05f_j)^2 + \sum (\Delta f_j)_n^2}$$

(c) A value of $0.10f_j$ is recommended if the actual computed value of Δf_j is less than $0.10f_j$. Figure N-1226-1 shows a sample of such a smoothed floor spectrum curve. Note that the broadened peak is bounded on each side by lines which are not vertical but parallel to the lines forming the original spectrum peak.

(d) An alternative method for the broadening of the structural peaks can be based on a probabilistic approach, as discussed in Ref. 40. In the particular case where there is more than one equipment or piping frequency located within the frequency range of a widened spectrum peak that is associated with a structural frequency f_j , the floor spectrum curve may be more realistically applied in accordance with the following criterion. Based on the fact that the actual natural frequency of the structure can possibly assume only one single value within the frequency range defined by $f_j \pm \Delta f_j$, but not a range of values, only one of these equipment or piping modes can respond with a magnitude indicated by the peak spectral value.

Therefore, seismic analysis of the equipment or piping systems using the broadened floor design response spectra may be accomplished by the following alternative method which can be used for equipment when analytical techniques are justified for predicting the natural frequencies.

Determine the natural frequencies $(f_e)_n$ of the system to be qualified in the broadened range of the maximum spectrum acceleration peak.

If no equipment or piping system natural frequencies exist in the $\pm 15\%$ interval associated with the maximum spectrum acceleration peak, then the interval associated with the next highest spectrum acceleration peak shall be selected and used in the following procedure.

Consider all N natural frequencies in the interval

$$f_j - 0.15f_j \leq (f_e)_n \leq f_j + 0.15f_j$$

where

f_j

= the frequency of maximum acceleration in the unbroadened spectra

n

= 1 to N

FIG. N-J226-1 RESPONSE SPECTRUM PEAK BROADENING AND PEAK AMPLITUDE

FIG. N-1226-1 RESPONSE SPECTRUM PEAK BROADENING AND PEAK AMPLITUDE

The system shall then be evaluated by performing $N + 3$ separate analyses using the unbroadened floor design response spectrum and the unbroadened spectrum modified by shifting the frequencies associated with each of the spectral values by a factor of +0.15; -0.15; and

$$\frac{(f_e)_n - f_j}{f_j}$$

where

$$n = 1 \text{ to } N$$

The resultants of these separate seismic analyses shall then be enveloped to obtain the final resultant desired (e.g., stress, support loads, acceleration, etc.) at any given point in the system. If three different floor spectrum curves are used to define the response in the two horizontal and the vertical directions, then the shifting of the spectral values as defined above may be applied to these three spectrum curves.

The criterion is illustrated by the following example. Figure N-1226-2, sketch (a) represents the peak broadening on the floor spectrum curve associated with the j th mode structural frequency. Let there be two equipment or piping frequencies $(f_e)_1$ and $(f_e)_2$ that are within the frequency interval of $f_j \pm 0.15f_j$, Fig. N-1226-2, sketch (b). Thus N equals two and therefore five separate floor response spectra must be considered. The unbroadened floor response spectrum as indicated in Fig. N-1226-2, sketch (a) would be the first floor spectrum considered. The unbroadened floor response spectrum modified by shifting all of the frequencies associated with the spectral acceleration values by a factor of -0.15 is illustrated in Fig. N-1226-2, sketch (c). In Fig. N-1226-2, sketches (d) and (e) illustrate the modifications made to the unbroadened floor response spectrum by shifting a factor of

$$\frac{(f_e)_1 - f_j}{f_j} \quad \text{and} \quad \frac{(f_e)_2 - f_j}{f_j}$$

respectively.

Figure N-1226-2, sketch (f) illustrates the modifications made to the unbroadened floor response spectrum by shifting by a factor of +0.15. For this example, the five separate seismic analyses are performed with the individually modified floor response spectrum curves.

The required resultants, stresses, support loads, accelerations, moments, forces, etc., associated with each of the five separate seismic analyses are then obtained. As any of the five modified spectra has an equal probability of occurrence, the resultant utilized to evaluate the seismic loadings shall be the envelope values from the five separate seismic analyses.

N-1227 Multiple Input Response Spectra Analysis

If a structural system is being analyzed by the response spectra method and is supported at intermediate locations with different characteristic response spectra, then the dynamic analysis performed should take into consideration the different response spectra. The effect of relative seismic anchor displacements between the intermediate anchor points should also be considered.

N-1227.1 Inertial Effects Due to Multiple Response Spectra Input.

The effect on a structural system of multiple supports with different characteristic response spectra may be accounted for by selecting a single spectra which will effectively produce the critical maximum responses due to different acceleration existing at anchor points and intermediate restraint points of the system. This may be conservatively accomplished by enveloping the response spectra for the different seismic anchor and restraint locations. Other procedures may be used, if applicable. Acceptable alternative procedures are given in Refs. 7, 43, 44, and 45.

For a structural system which is restrained in different buildings, the response spectra of the restraint point should be enveloped.

N-1227.2 Stresses Due to Relative Seismic Support Displacements

(a) When determining stresses the effects of relative seismic support movements should be considered. When these effects are considered significant, they may be obtained by performing a static structural analysis of the system including anchor movements. For structural systems with several possible combinations of anchor movements, any of the following methods may be used for determining the stresses due to relative support displacements.

(1) Stresses resulting from the differential movement of supports may be calculated for each significant mode using the modal displacement of the supports obtained from the structural response calculations. The maximum model responses are then combined following any of the acceptable methods described in this Appendix. If no support structure modal information is available, then the absolute sum of the displacements may conservatively be used.

(2) If the system is supported on independent structures, then the absolute sum of displacements in

Page 380

each direction should be used unless more detailed analyses are used in accordance with N-1700. Pages 381-381

FIG. N-1226-2 USE OF FLOOR SPECTRA WHEN SEVERAL EQUIPMENT FREQUENCIES ARE WITHIN THE WIDENED SPECTRAL PEAK

FIG. N-1226-2 USE OF FLOOR SPECTRA WHEN SEVERAL EQUIPMENT FREQUENCIES ARE WITHIN THE

FIG. N-1226-2 USE OF FLOOR SPECTRA WHEN SEVERAL EQUIPMENT FREQUENCIES ARE WITHIN THE WIDENED SPECTRAL PEAK (CONT'D)

FIG. N-1226-2 USE OF FLOOR SPECTRA WHEN SEVERAL EQUIPMENT FREQUENCIES ARE WITHIN THE WIDENED SPECTRAL PEAK (CONT'D)

(3) If a displacement time history of the supporting structure is available, the procedures given in N-1228.4 may be used.

(b) Other detail considerations may be specified for dynamic analysis of Section III components, such as NB-3600 for piping, and these component related rules should be considered in the dynamic analysis.

N-1228 Multiple Time History Excitations

For structural systems supported at several locations, the responses due to simultaneous excitations by different motions at each support may be determined exactly by time history methods, as in N-1228.1. Having performed a time history response analysis, reaction loads and motions may also be determined on a time history basis, as in N-1228.2. Since the inertial effects may be considered to produce primary stresses and the differential support motions may be considered to produce secondary stresses, as in NB-3650, the inertial effects may be determined separately from the differential support movement effects, as in N-1228.3.

N-1228.1 Time History Response Analysis

(a) Several different acceptable methods have been presented in the literature (Refs. 7, 43, and 44) for solving the equations of motion for a structural system excited by multiple simultaneous forcing functions. Since the basic problem to be solved must satisfy the fundamental principles of dynamics, the differences between the various methods are primarily in the approach of the solution process. One method of solution is summarized here to provide insight into the basics of time history analysis for multiple excitations.

(b) The general matrix form of the undamped coupled equations of motion may be written (Refs. 7 and 45) as follows:

$$(32) MX'' + KU = F$$

where X'' represents the absolute acceleration of the mass point dynamic degrees of freedom, and U represents

Page 382

those displacements of the mass and support point dynamic degrees of freedom which would tend to cause distortions in the system. Rigid body translations or rotations are included in the mass acceleration terms on the left-hand side of the equation. Such rigid body motions would not tend to distort the system and accounted for by defining one of the system support points to be the *datum* support, and describing the motion of all other *nondatum* supports as motions relative to the datum support.

(c) Equation (32) can be expanded to give

$$\begin{bmatrix} M_m & 0 \\ 0 & M_s \end{bmatrix} \begin{Bmatrix} X''_m \\ X''_s \end{Bmatrix} + \begin{bmatrix} K_{mm} & K_{ms} \\ K_{sm} & K_{ss} \end{bmatrix} \begin{Bmatrix} U_m \\ U_s \end{Bmatrix} = \begin{Bmatrix} 0 \\ F_s \end{Bmatrix} \quad (33)$$

(33)

where

M_m

= a diagonal submatrix of the system model lumped masses

M_s

= a submatrix of inertia terms associated with the support joints of the system. For the purposes of this analysis, $M = 0$ because there is no mass lumped at support joints

F_s

= the reaction forces at the system support points due to the response of the system to the motion of the support structure

K

= the stiffness matrix of the system model condensed in a manner such that only mass point elements (subscript m) and active, nonreleased, nondatum support elements (subscript s) remain in the matrix

U_m

= displacement of mass point dynamic degrees of freedom relative to the datum support in each coordinate direction

U_s

= displacement of nondatum. support points relative to the datum support

X''_m

= absolute acceleration of mass point dynamic degrees of freedom of the model

X''_s

= absolute acceleration of the system support points

(d) The time history support motions imposed at the nondatum supports include only such displacements as would tend

to cause distortions in the system. Rigid body translation or rotation of the supporting structure would not distort the system being analyzed; therefore, such rigid motions of the supporting structure are removed by computing the nondatum support relative motions as follows:

$$(34) U_s = X_s - X_d - R_s \theta$$

where

U_s	= displacements of nondatum support points relative to the datum support in each direction of excitation
X_s	= absolute displacements of nondatum supports in each direction of excitation
X_d	= absolute displacements of datum supports in each direction of excitation
R_s	= a matrix of three vectors representing distances from the datum support point of the nondatum support points
θ	= rigid body rotations of the supporting structure about each of the three coordinate axes

(e) The first equation of the set of Eqs. (33) yields:

$$(35) M_m X_m'' + K_{mm} U_m + K_{ms} U_s = 0$$

(f) A separation of variables can be achieved by defining the absolute acceleration of a mass point in terms of acceleration relative to the datum support, such that:

$$(36) U_m'' = X_m'' - \gamma X_{sd}'' - R_m \theta''$$

where

γ	= matrix defining the direction of each respective translational dynamic degree of freedom such that:
γ_{ij}	= 1, if the i th dynamic degree of freedom is in the direction of the j th direction of support translation
γ_{ij}	= 0, if the i th dynamic degree of freedom is not in the direction of the j th direction of support translation
X_{sd}''	= the absolute accelerations of the datum support in each coordinate direction
R_m	= a matrix of three vectors representing distances from the datum support point to the mass points for each of the rotational components
θ	= rotational accelerations of the datum support (g) Equation (35) then becomes

$$(37) M_m U_m'' + K_{mm} U_m = -M_m X_{sd}'' - M_m R_m \theta'' - K_{ms} U_s$$

(h) At this point it is to be noted that the equations of motion are in a form expressing three dimensional response of the system mass points due to multiple translational and rotational support excitations in one or more coordinate directions. Normally, the rotations will consist of two components representing rocking about two orthogonal horizontal coordinate axes. The equations, however, are also valid for rotation about the vertical axes. It should be noted again that U

(i) The coupled equations of motion, Eq. (37), may be solved by one of the methods of direct integration, or, introducing the normal mode coordinate transformation:

$$(38) U_m = \phi q$$

where

$$\begin{array}{ll} \phi & = \text{the matrix of eigenvectors of the supported system} \\ q & = \text{the normal mode coordinate} \end{array}$$

(j) Then making the usual assumption of proportional damping for the modes of the supported system, the equations of motion can be uncoupled and written in the following form:

$$\begin{aligned} q'' + 2\xi\omega q' + \omega^2 q = & \\ & - (\phi' M_m \phi)^{-1} (\phi' M_m \gamma X''_{sd} \\ & + \phi' M_m R_m \theta' + \phi' K_{ms} U_s) \end{aligned} \quad (39)$$

(39)

where

$$\begin{array}{ll} \omega^2 & = \text{diagonal matrix of eigenvalues} \\ 2\xi\omega & = \text{diagonal matrix of modal damping terms} \end{array}$$

(k) The right-hand side of Eq. (39) contains no damping terms in a rigorous sense only if the modal damping is proportional to stiffness. However, Ref. 46 points out that the contribution of these terms to earthquake forces can be expected to be small. This term is usually neglected for systems exhibiting structural damping characteristics within the range of the values in Table N-1230-1.

N-1228.2 Time History Reaction Analysis

(a) Having solved the dynamics problem for the time histories of the mass point motions, the resultant reactions at locations throughout the system can be determined for each time step by imposing the deflections on the structure in a series of static problems; one static solution for the deflected shape at each time step. Although this approach is analytically valid, it is generally not practical because of the many thousands of solutions required for the number of time steps in a typical seismic analysis. The problem may be reduced to a single static deflection analysis by applying unit displacements to each mass and support point to determine a set of influence coefficients for each desired reaction. The given support displacements and computed mass point displacements at each time step are multiplied by the set of

influence coefficients to perform a complete reaction analysis of the system at each time step.

(b) The desired components of reaction (force, moment, stress, or deflection) are computed at each time step as follows:

$$(40) R(t) = C_m U_m(t) + C_s U_s(t)$$

where

$R(t)$	= a vector of reaction components at time t
C_m	= a matrix of mass point unit displacement influence coefficients (one column per mass point and one row per reaction component)
C_s	= a matrix of nondatum support point unit displacement influence coefficients (one column per nondatum support and one row per reaction component)
$U_m(t)$	= a vector mass point relative displacements at time t
$U_s(t)$	= a vector of nondatum support relative displacements at time t

(c) In a similar manner, the absolute acceleration of any point in the system may be computed by multiplying the mass point and support relative accelerations by the influence coefficients for displacement reactions, and adding in the datum support rigid body rotational and translational absolute accelerations as follows:

$$R''(t) = \gamma X''_{sd}(t) + C_m U''_m(t) + C_s U''_s(t) + R_p \theta''(t) \quad (41)$$

(41)

where

$R''(t)$	= a vector of absolute acceleration components at time t
$X''_{sd}(t)$	= the translational absolute acceleration of the datum support at time t
C_m	= a matrix of mass point unit displacement influence coefficients for components of displacement reactions
$U''_m(t)$	= a vector of mass point accelerations relative to the datum at time t
C_s	= a matrix of nondatum. support unit displacement influence coefficients for components of displacement reactions
$U''_s(t)$	= a vector of nondatum support relative accelerations at time t
γ	= a vector defining the direction of excitation, such that:
γ_{ij}	= 1, if the j th component of reaction is in the direction of j th support motion

R_P	= 0, if the jth component of reaction is not in direction of the jth support motion = a matrix containing distances to the reaction point from the datum
-------	--

$\theta'(t)$	= the rotational absolute acceleration of the datum support at time t
--------------	---

(d) This method, therefore, permits the calculation of any desired force or moment, or nonmass point motion on a time history basis.

(e) The ability to calculate time history acceleration of nonmass locations in the system permits the subsequent generation of response spectra at any arbitrary point in the system without the necessity of lumping mass at these points.

N-1228.3 Separation of Inertial and Relative Anchor Movement Stress Effects

(a) The terms of the C_s coefficients matrix can be found by applying a unit displacement to each nondatum support in turn, holding all other supports and mass points fixed, and calculating the desired reaction at a given location. The reactions found in this manner are the combined effect of inertial and relative displacement stress producing effects, suitable for meeting the appropriate Code requirements, such as Eq. (10) of NB-3653.1 for Class 1 piping.

(b) Alternatively, one may break up the C terms into two terms C_{s1} and C_{s2} such that

$$(42) R(t) = C_m U_m(t) + C_{s1} U_s(t) + C_{s2} U_s(t)$$

or

$$(43) R_1(t) = C_m U_m(t) + C_{s1} U_s(t)$$

and

$$(44) R_2(t) = C_{s2} U_s(t)$$

where

$R_1(t)$	= a vector of stress reaction components at time t due to inertial responses
$R_2(t)$	= a vector of stress reaction components at time t due to relative support motions
C_{s1}	= a matrix of influence coefficients due to holding all supports fixed and applying the set of forces to all mass points which would be required to hold the mass point in place due to a unit displacement of each nondatum support in turn
C_{s2}	= a matrix of influence coefficients to a unit displacement of each nondatum support in turn, allowing all mass points to respond freely as static degrees of freedom in the structure

FIG. N-1228.3-1 COEFFICIENTS FOR A COMPONENT OF SHEAR FOR A UNIT DISPLACEMENT OF A NONDATUM SUPPORT

FIG. N-1228.3-1 COEFFICIENTS FOR A COMPONENT OF SHEAR FOR A UNIT DISPLACEMENT OF A NONDATUM SUPPORT

(c) The coefficients for a component of shear for a unit displacement of a nondatum support may be visualized as shown in Fig. N-1228.3-1.

(d) The C_{s1} term therefore represents inertial effect produced by the differential support motion, and the C_{s2} term represents the relative displacement effect of the differential support motion. The separate stresses determined in this manner may be used to meet the appropriate Code requirements, such as Eq. (9) of NB-3652 for Class 1 piping.

N-1228.4 Envelope Excitations

(a) Where the responses are calculated using a single time history excitation for a multiply supported system, the response spectrum of the single time history used should envelop the spectra for the individual support motions. The secondary stress effects of differential support motions may then be determined by a separate static analysis where either:

(1) the set of maximum displacements over all time for each support are applied simultaneously in a single analysis; or

(2) the displacements of each support are applied to perform an analysis for each time step, accounting for sign.

(b) Where the maximum displacements over all time are used in a single analysis, then:

(1) for systems supported at multiple locations on the same floor/wall where one flexural mode dominates, the relative displacement set for the dominant mode may be used, where justified;

(2) for systems supported at multiple locations on different floor/walls or on different structures where different flexural modes can dominate, the displacement may be applied statically as prescribed in N-1227.

(c) Note that, in general, different support displacement sets may be required to obtain conservative

secondary stress effect at different locations within a system, depending on the complexity of a given system.

N-1230 DAMPING

N-1231 Damping Values

(a) Motions in a structural system will dissipate energy from the system. The phenomenon of this kind of energy loss is called damping. In a structural system, sources of energy loss may be due to: a structural damping, which is caused by internal friction within the material or at connections between elements of a structural system; a viscous damping, which is caused by motions in a fluid; Coulomb damping which results from the sliding friction motion of a body on another surface. The following equation of motion is generally used for structural systems and components:

$$(45) [M] \{X''\} + \{D\} + [K] \{X\} = \{F\}$$

where

M	= mass matrix
K	= stiffness matrix
D	= damping force vector
X	= displacement vector
X'	= velocity vector
X''	= acceleration vector
F	= force vector

(b) The damping force $\{D\}$ represents the energy losses of the system. To evaluate these losses, the following alternative mathematical expressions are recommended for the vector $\{D\}$.

(1) Viscous damping:

$$(46) \{D\} = [C] \{X'\}$$

where $[C]$ is a viscous damping matrix. The damping force is proportional to the velocity.

(2) Hysteretic damping:

$$(48) \{D\} = i\nu[K] \{X\}$$

where ν represents the structural damping factor (Ref. 47). This damping is also called complex damping. The damping force is proportional to the amplitude of the displacement and opposite in direction to the velocity:

$$(48) \{D\} = g(abs[K] \{X\}) sgn \{X'\}$$

where g is a damping coefficient (Ref. 48). This damping is also called the Reid's damping. The damping force is proportional to the resisting force due to deformation and in the opposite direction of the velocity in harmonic motion.

**TABLE N-1230-1
DAMPING VALUES
Percent of Critical Damping**

Structure or Component	Earthquake Magnitude	
	Operating Basis Earthquake	Safe Shutdown Earthquake
Equipment and large diameter piping systems, ¹ > 12 in. diam.	2	3
Small diameter piping systems, ≤ 12 in. diam.	1	2
Welded steel structures	2	4
Bolted steel structures	4	7
Prestressed concrete structures	2	5
Reinforced concrete structures	4	7

NOTE:

(1) Includes both material and structural damping. If the piping system consists of only one or two spans, with little structural damping, use values for small diameter piping.

TABLE N-1230-1 DAMPING VALUES Percent of Critical Damping

(3) Coulomb damping:

$$(49)\{D\} = \pm \mu \{N\}$$

where μ is the coefficient of friction and N is the normal force vector. The sign is chosen to be opposite the velocity. The damping force is due to friction and proportional to the normal force.

(4) General dashpot damping:

$$(50) \{D\} = \alpha \{X\} (\text{abs}\{X\})^{n-1}$$

where α is a damping constant and n is an integer. This damping force is due to the turbulence and the dashpot geometry.

(c) These expressions permit the simulation of the energy loss for a particular problem. It is extremely difficult to give an accurate analytical expression for the different forms of damping in complex structural systems. The analyst may select a simple expression, such as viscous or hysteretic damping, to solve the problem by assuming that the energy losses are equivalent; i.e., viscous damped system introduced in the analysis will have the same energy loss per cycle as the real structure.

Page 386

(d) To establish an equivalent viscous damping matrix $[C]$ for the system, experimental data is usually required. Important experimental results, which indicate that energy losses increase with stress or displacement amplitude, or both, have been compiled in existing literature (Refs. 49 and 50). The incorporation of this behavior to the equivalent viscous damping in the transient analysis will usually lead to an expression of the damping force which will make the equations of motion nonlinear. To avoid this inconvenience, conservative modal damping values may be used for nuclear systems and structures for OBE and SSE condition loads, respectively. Table N-1230-1 shows the modal damping values recommended. Damping values higher than the ones given in Table N-1230-1 may be used in a dynamic analysis if the basis is justified.

(e) Methods of incorporating the damping in structural dynamics are usually dependent on the mathematical convenience. The energy loss per cycle is simulated by a convenient mathematical scheme; frequently viscous damping expressions are adopted in the analysis. In N-1232 and N-1233, methods of proportional and nonproportional dampings are discussed and the physical interpretations associated with each method is also examined.

N-1232 Proportional Damping

(a) Consider a viscously damped system of the following form:

$$(51) [M] \{X''\} + [C] \{X'\} + [K] \{X\} = \{F\}$$

Let $[\phi]$ be the modal matrix of the undamped system of

$$(52) [M] \{X''\} + [K] \{X\} = \{0\}$$

such that

$$(53) [\phi]^T [M] [\phi] = [I]$$

and

$$[\phi]^T [K] [\phi] = [\omega^2]$$

where

$[\phi]^T$	= transpose of the matrix $[\phi]$
I	= identity matrix
ω^2	= diagonal matrix
ω_i	= circular frequencies

(b) If the matrix $[C]$ in Eq. (51) can be diagonalized by the undamped normal modes (i.e., $[\phi]^T [C] [\phi]$ is a diagonal matrix), then the damping matrix $[C]$ is called the proportional damping matrix; otherwise, it is called the nonproportional damping matrix.

(c) Reference 52 has illustrated that the matrix $[C]$ can be diagonalized when it is a linear combination of $[M]$ and $[K]$ matrices. Caughey (Ref. 53) has derived more general conditions under which the matrix $[C]$ can be diagonalized.

(d) For proportional damping the equations of motion may be uncoupled into a set of independent one degree of freedom systems. In this case, the damping ratio associated with the different modes can be determined.

(e) Among the category of proportional dampings, two types of damping matrix $[C]$ are commonly adopted; namely, the

mass and stiffness damping and the orthogonal modal damping. Both types of damping are discussed in N-1232.1 and N-1232.2.

N-1232.1 Mass and Stiffness Damping (Ref. 53)

(a) In this damping, the matrix $[C]$ is assumed to be proportional either to the mass matrix $[M]$ or to the stiffness matrix $[K]$ or to a linear combination of the two. That is, it can be written as follows:

$$(54) [C] = \alpha[M] + \beta[K]$$

where

α and β	= two real constants
$\alpha[M]$	= mass damping
$\beta[K]$	= stiffness damping

(b) In using the mass and stiffness damping, damping values of the entire system are determined by the two constants α and β . To determine the value of α and β , one can control the damping ratios for two frequencies.

(c) Let ω_r and ω_s be the two frequencies that we want to have a damping ratio of ξ_r and ξ_s respectively. Then α and β may be determined (Ref. 54) as follows:

$$\begin{aligned}\alpha &= 2\omega_r\omega_s(\xi_s\omega_r - \xi_r\omega_s)/(\omega_r^2 - \omega_s^2) \\ \beta &= 2(\xi_r\omega_r - \xi_s\omega_s)/(\omega_r^2 - \omega_s^2)\end{aligned}\tag{55}$$

(55)

Then, for an arbitrary frequency ω_i the damping ratio ξ_i can be computed by eliminating α and β and is given as:

$$\begin{aligned}\xi_i &= \frac{1}{(\omega_r^2 - \omega_s^2)} \left[\frac{\omega_r\omega_s}{\omega_i} (\xi_s\omega_r - \xi_r\omega_s) \right. \\ &\quad \left. + \omega_i(\xi_r\omega_r - \xi_s\omega_s) \right]\end{aligned}\tag{56}$$

(56)

where

is due to mass damping and.

$$\frac{1}{(\omega_r^2 - \omega_s^2)} \times \omega_i (\xi_r \omega_r - \xi_s \omega_s)$$

is due to stiffness damping.

(d) The application of the mass and stiffness damping concept is illustrated by a following numerical example. Consider a structural system with frequencies of $f_n = n$ Hz for $n = 1, 2, \dots, 25$. For a damping ratio of $\xi_{10} = 0.05 = \xi_{20}$ at frequencies $f_{10} = 10$ Hz and $f_{20} = 20$ Hz and by using Eq. (56), the damping ratios for the other modes may be computed. For example, at the frequencies of 5, 15, and 25 Hz, the corresponding damping ratios are $\xi_5 = 0.075$, $\xi_{15} = 0.047$, and $\xi_{25} = 0.055$.

(e) It should be noted that in Eq. (56), the damping ratio is the sum of the contributions due to the mass and stiffness damping. Using mass damping $\alpha \neq 0$, $\beta \neq 0$, the damping ratio will decrease with increase of the frequency. On the other hand, using stiffness damping $\alpha = 0$, $\beta \neq 0$, the damping ratio will increase with the increase of the frequency.

(f) Mass damping introduces the damping forces that are proportional to the velocities of each mass point in the system. Mass damping may be used to represent the energy loss due to impact and friction. Stiffness damping introduces the damping forces that are proportional to the time rate of deformation. Stiffness damping can be used to represent the structural damping. While the mass damping introduces the damping forces due to the rigid body motion (displacements without deformations) of the system, the stiffness damping does not.

(g) In seismic analysis of a structural system, the equation of motion is generally formulated in terms of the displacements with respect to the base. If the damping ratios are established for the two significant frequencies, the mass and stiffness dampings may be adopted. The damping ratios for the other frequencies are computed with the aid of Eq. (56). If only stiffness damping is used, and for the significant frequency Ω_r , the established damping ratio is ξ_r , then

$$\beta = \frac{2\xi_r}{\omega_r} \text{ and } \xi_i = \xi_r \frac{\omega_i}{\omega_r}$$

where ξ_i is the damping ratio for the modal frequency ω_i .

N-1232.2 Orthogonal Modal Damping (Ref. 54).

In the orthogonal modal damping method, the damping matrix $[C]$ in Eq. (51) is not formulated in advance. After solving the eigenvalue problem, the system or uncoupled equations are assumed to have the form

$$q''_i + \xi_i(2\omega_i)q'_i + \omega_i^2 q_i = f_i$$

$$i = 1, 2, \dots, N \quad (57)$$

(57) where the second term in Eq. (57) is added to account for the damping. The damping ratio for each frequency is free to be determined by the analyst without any mathematical restriction. The damping ratio assigned to one mode will have no effect on the damping ratios of the others; the modes are orthogonal. These ratios can be obtained from the experimental results. This method is used often in solving viscously damped systems. The example problems for the various damping methods discussed here are given in Ref. 55.

N-1233 Nonproportional Damping

In the foregoing discussion of the proportional damping (N-1232), the damping of a structural system was assumed to have a form that couplings do not exist between the classical modes of vibrations; i.e., the mode shapes obtained from the solution of a free vibration of the undamped system. This approach is appropriate for the correlation of test data for a structural system composed of a single material, or damping mechanism which is homogeneous throughout the system. However, for a system which is composed of different materials, such as a reactor coolant loops, containment building, and soil foundation, the damping mechanism of one type of material may be considerably different from the other. In order to have a better simulation of the damping, it is useful to construct a damping matrix which reflects the material composition rather than the mathematical convenience (Refs. 56 and 57). The damping matrix so constructed will no longer be diagonalized by the classical modes. The term *nonproportional damping* is used for this type of damping. In nonproportional damping, the matrices $[M]$, $[K]$, and $[C]$ are used to solve the complex frequencies and mode shapes. From the complex frequencies, damping ratios associated with each mode can readily be computed. Unlike proportional damping, the matrix

[C] of a nonproportional damping system cannot be formulated simply by specifying a set of damping ratios, unless a mathematical process of successive approximations is performed. Due to the mathematical complexity involved in the complex frequencies and mode shapes solution, the process of assigning a set of damping ratios with respect to the complex modes becomes impractical. For certain types of structures such as reactor coolant loops, the system exhibits a pronounced modal behavior (Ref. 58). Instead of using a set of damping ratios based on the complex frequencies and modes, the classical modes and frequencies may be used to avoid the mathematical complexity. N-1233.1 and N-1233.2 describe acceptable methods for the formulation of a nonproportional damping matrix for a structural system which is composed of different materials.

N-1233.1 Composite Mass Damping and Stiffness Damping

(a) In the proportional damping, Eq. (51) of N-1232, the system damping matrix is assumed to be a linear combination of the system mass and stiffness matrices, without any distinction of the material damping property. Different sets of proportional constants for mass and stiffness may be assumed to formulate a system damping matrix. Using the concept of mass and stiffness damping, the energy dissipation function D for the system can be written as follows:

$$D = \frac{1}{2} \sum_{i=1}^{nc} (\alpha_i \{X'\}_i^T [M]_i \{X'\}_i + \beta_i \{X'\}_i^T [K]_i \{X'\}_i) \quad (58)$$

(58)

where

$[M]_i$	= mass matrix of subsystem i
$[K]_i$	= stiffness matrix of subsystem i
α_i	= mass proportional constant of subsystem i
β_i	= stiffness proportional constant of subsystem i
nc	= number of subsystems

For the systems with constant damping values, α_i and β_i are the same for all elements. However, when the system is composite, which consists of subsystems with different damping values, α_i and β_i are different for different subsystems but constant within each subsystem. These constants may be established for each subsystem as discussed in N-1232.1.

(b) This decomposition to allow different damping constants α_i and β_i to be used for each different subsystem may be based on the damping values recommended in Table N-1230-1.

(c) To determine the constants α_i and β_i , the frequencies and modes of the free undamped vibration of the i th subsystem are used as a basis. The mathematical process involved is similar to the one of stiffness and mass damping described in N-1232.1 except the constants α and β are different for each material or subsystem.

(d) Using Eq. (58), the equation of motion of a viscously damped system has the following form:

$$[M]\{X'\} + \sum_{i=1}^{nc} (\alpha_i[M]_i + \beta_i[K]_i)\{X'\} + [K]\{X\} = \{F\} \quad (59)$$

(59)

(e) Equation (59) may be integrated directly to obtain the response. If normal mode method is used, Eq. (59) may be solved by neglecting the modal coupling effect to decouple the equations of motions on the normal mode basis.

(f) Let $\{\phi\}$ be the modal matrix of the undamped system of Eq. (59) and $\{\phi_j\}$ be the j th modal vector. With the aid of the orthogonality conditions, the equation of motion for the j th mode can be written in the following form:

$$\begin{aligned} & \{\phi_j\}^T [M] \{\phi_j\} q''_j + \{\phi_j\}^T \sum_{i=1}^n (\alpha_i[M]_i + \beta_i[K]_i) \{\phi\} \{q'_j\} \\ & + \{\phi_j\}^T [K] \{\phi_j\} q_j = \{\phi_j\}^T \{F\} \end{aligned} \quad (60)$$

(60)

where q''_j is the j th generalized coordinate. The second term on the left-hand side of Eq. (60) contains the coupling terms. If these coupling terms are neglected, Eq. (60) reduces to the following equation:

$$[\phi_j]^T [M] \{\phi_j\} \ddot{q}_j + \{\phi_j\}^T \sum_{i=1}^n$$

$$(\alpha_i [M]_i + \beta_i [K]_i) \{\phi_j\} \dot{q}_j$$

Page 389

$$+ \{\phi_j\}^T [K] \{\phi_j\} q_j = \{\phi_j\}^T \{F\} \quad (61)$$

(61)

or

$$\begin{aligned}
 q''_j + 2w_j \left(\frac{\sum_{i=1}^{nc} \{\phi_j\}^T \alpha_i [M]_i \{\phi_j\}}{2\omega_j \{\phi_j\}^T [M] \{\phi_j\}} \right. \\
 \left. + \frac{\sum_{i=1}^{nc} \omega_j \{\phi_j\} \beta_i [K]_i \{\phi_j\}}{2\{\phi_j\}^T [K] \{\phi_j\}} \cdot q_j \right) \\
 + \omega_j^2 q_j = \frac{\{\phi_j\}^T \{F\}}{\{\phi_j\}^T [M] \{\phi_j\}} \quad (62)
 \end{aligned}$$

(62)

Consequently, the effective damping for the j th mode is as follows:

$$\xi_j = \frac{\sum_{i=1}^{nc} \{\phi\}^T \alpha_i [M]_i \{\phi_j\}}{2\omega_j \{\phi_j\}^T [M] \{\phi_j\}} + \frac{\sum_{i=1}^{nc} \omega_j \{\phi_j\}^T \beta_i [K]_i \{\phi_j\}}{2\{\phi_j\}^T [K] \{\phi_j\}} \quad (63)$$

(63)

or

$$\xi_j = \frac{\sum_{i=1}^{nc} \alpha_i \left(\begin{array}{c} \text{max. kinetic energy for } i\text{th} \\ \text{subsystem in the } j\text{th mode} \end{array} \right)}{2\omega_j (\text{max. kinetic energy for the system})} + \frac{\sum_{i=1}^{nc} \beta_i \left(\begin{array}{c} \text{max. strain energy for } i\text{th} \\ \text{subsystem in the } j\text{th mode} \end{array} \right)}{2 (\text{max. strain energy for the system})} \quad (64)$$

(64)

(g) Equation (63) can be greatly simplified if either α_i or β_i is assumed to be zero. This assumption may be used in the structural analysis for seismic loads where damping is generally assumed proportional either to the kinetic energy distribution of the subsystems or to the strain energy stored.

(h) Once the damping ratio ξ_j is known, the analysis can be carried out using a time history or response spectrum technique.

N-1233.2 Subregional Modal Damping

(a) In dynamic analysis of soil-structure interaction, the modal damping value of the soil is often higher than that of the superstructure. In addition, the modal damping values of the various subsystems, building, loop, etc., of the superstructure may be different. There are several acceptable approximate methods to simulate this subregional modal damping characteristic. These methods are briefly discussed here. One method from Ref. 15 is to relate composite damping to absolute displacement Eq. (65), while another method (Ref. 59) is to relate it to relative displacement Eq. (66):

$$\xi_j = \frac{\sum_{i=1}^{nc} \{\phi_j\}^T \beta_i [M]_i \{\phi_j\}}{\{\phi_j\}^T [M] \{\phi_j\}} \quad (65)$$

$$\xi_j = \frac{\sum_{i=1}^{nc} \{\phi_j\}^T \beta_i [K]_i \{\phi_j\}}{\{\phi_j\}^T [K] \{\phi_j\}} \quad (66)$$

(65 - 66)

where

ξ_j	= % critical damping for j th mode
nc	= number of subsystems
$\{\phi_j\}$	= j th eigenvector
$[M]$	= total system mass matrix
$[K]$	= total system stiffness matrix
$[M]_i$	= mass matrix of i th subsystem
$[K]_i$	= stiffness matrix of i th subsystem
β_i	= % critical damping associated with i th subsystem

(b) Another acceptable approximate method employs mass and stiffness damping for each subsystem. This method calculates coefficients α and β , Eq. (55) of N-1232, for a subsystem such that its modal damping is simulated in the frequency range of interest. The damping matrices of all the subsystems are assembled to formulate a total system damping matrix. Another acceptable approach to generate a total damping matrix is discussed in Ref. 62.

(c) All the methods discussed above are approximate. More accurate techniques are also acceptable. A more rigorous method to formulate a damping matrix for a total system is based on the modal synthesis procedure. This procedure is

explained by Hurty (Ref. 56). Various investigators have developed another method (Ref. 63) modifying this procedure. In this procedure, the total system having nonproportional damping is divided into subsystems, each having proportional damping. Each subsystem is represented by its modal mass, damping, and stiffness matrices. As each subsystem has a proportional damping, the associated modal damping matrix is formulated without any approximation. The modal matrices of all the subsystems are assembled and the displacement compatibility at subsystem interfaces are satisfied. The resulting equations of motion are solved

Page 390

and with the aid of a transformation matrix, actual response is obtained. References 57, 64, and 65 give the details of the application of this method.

(d) The total damping matrix developed by the preceding methods represents the viscous damping. An acceptable alternative formulation for damping, derived in Ref. 66, is an equivalent modal damping ratio which represents the viscous damping in the swaying spring and the hysteretic damping in the rest of the soil-structure system (the superstructure and the rocking spring).

N-1234 Linear Hysteretic Damping

(a) In this paragraph the linear hysteretic damping of the Reid's model (Ref. 48) will be discussed. This nonlinear model leads to well posed mathematical problems for transient and steady-state oscillations of all kinds. The damping forces of the Reid's model are assumed to be proportional to the internal forces of the structure but in phase with the associated velocities. By using the Reid's damping model, the equation of motion [Eq. (45) of N-1231] becomes:

$$(67) [M]X'' + g \{ (abs [K] \{X\}) \times (sgn \{X'\}) \} + [K] \{X\} = \{F\}$$

where

g	= damping coefficient
$abs[K] \{X\}$	= the absolute value of each component
$sgn\{X'\}$	= the algebraic sign of the velocity $\{X'\}$

(b) The Reid's damping model has the following characteristics (Ref. 67):

(1) the energy loss per cycle in a harmonic motion is proportional to the coefficient g and square of the amplitude of displacement and independent of the frequency;

(2) for light damping ($g^2 \ll 1$) the Reid's damping model will be equivalent to the classical modal damping with a damping ratio of $\xi = g/2\pi$ for each mode of vibration.

(c) Similar to the case of composite mass damping and stiffness damping, the damping coefficient g in Eq. (67) may also be considered as the elemental basis for a structural system which is composed of materials with different damping values.

N-1300 FLOW-INDUCED VIBRATION OF TUBES AND TUBE BANKS

N-1310 INTRODUCTION AND SCOPE

The flow-induced vibration (FIV) potential of structures has been known for a long time (Refs. 79 through 84). FIV analyses are required to determine the adequacy of a design, or in areas of uncertainty, to be aware of the need for experimental verification (Refs. 85 and 86) if high reliability of the component is a necessity. FIV may be due to any one of several excitation mechanisms because power systems include many types of flexible components subject to a variety of fluid flows, such as pipe, channel, and jet flows followed by mixing in plenums and heat exchangers. Since a single component is often subjected to different turbulent flows from several directions because of the influence of adjacent structures and boundaries, FIV analyses for more than one excitation mechanism is not unusual.

The quantitative data and correlations available to perform FIV analyses are unique to the flow geometry created by each component. More quantitative information and design methods are available for some components than others. In particular, the circular cylinder has been studied most. N-1320 through N-1340 of this Appendix are presented to illustrate one or more acceptable steps for the FIV analysis of arrays of cylinders subject to the three most significant excitation mechanisms. The

general methods employed are applicable to other types of components, but the data are specifically for single cylinders and cylindrical arrays. Because of the large number of FIV mechanisms, the methodology of analysis is referenced, but enough information is given to understand a mechanism and make design calculations. Because of the developing nature of the subject, more than one set of design data or methods may be recommended with the implication to the designer to use either the more appropriate or the more conservative predictions.

Semiempirical correlations based on experimental data, but guided by the equations of motion, often form the basis of a design method. The state-of-the-art regarding description of the FIV mechanisms is that many mathematical models have been proposed for fluid-structure coupling forces, but general agreement on the physics of many of the phenomena has not been attained, although models simulating the behavior may be available.

N-1311 Definitions

In this section some commonly used terminologies in flow-induced vibration analysis are defined and briefly described.

Page 391

(a) *Fluid forces* can be defined into two broad categories to describe FIV excitation mechanisms (Refs. 79 through 83). Fluid excitation forces are created by the incident flow on a structure, and they would occur, in some form, even without structural motion. Fluid structure coupling forces are induced by structural motion, and they occur in both flowing and nonflowing fluids.

(b) *Added mass and added damping* have been successfully used to characterize the fluid-structure coupling forces created by the motion of a structure in a nonflowing fluid (Refs. 87 through 93)). Added mass and added damping increase the effective mass and damping of a structure vibrating in a fluid. In addition, the presence of a dense fluid between otherwise unconnected, adjacent structures can couple their vibrations and result in significantly different natural frequencies, mode shapes, and damping from those obtained in a vacuum. For a low density fluid (e.g., air); the added mass is often negligible.

(c) In a *weakly coupled fluid-structure system*, the FIV excitation mechanism causes small structural motion and the fluid forces induced by the structural motion can be linearly superimposed onto the fluid excitation forces which are largely independent of the structural motion. The fluid-structure coupling forces can be expressed to a first order of approximation in terms of added mass, stiffness, and damping matrices. The fluid excitation forces can be determined separately from the coupling forces either by analysis or by model tests with only the hydraulics simulated.

Examples of FIV excitation mechanisms producing weakly coupled fluid-structure systems are incident flow turbulence and turbulent boundary layers over rods, plates, and shells (Refs. 81 and 82)); some wake flows produced by flow across bluff bodies; and many sources of acoustic noise (Refs. 80 and 95)). In these cases, the fluid excitation energy is generated at some point in the fluid circuit and the structure is the recipient of the energy. The forces due to flow turbulence and attached boundary layers typically are broadband random, while separated wake flows that roll into periodically shed vortices can produce very discrete frequency forces (Refs. 82, 87, and 97).

(d) In a *strongly coupled fluid-structure system*, the FIV excitation mechanism causes the structural motion to become large enough to change the flow field; some of the fluid forces amplify, rather than inhibit, the structural motion that produced them. Clearly distinguishing between fluid-structure coupling forces and fluid excitation forces is difficult in strongly coupled fluid-structure systems. In general, the coupling forces are highly nonlinear functions of structural motion and flow velocity.

(e) *Fluid-elastic instability* of closely packed heat exchanger tube bundles (Refs. 80, 81, 82, and 88) is an example of a strongly coupled fluid-structure system. The motion of each tube affects the fluid forces and the motion of the other tubes to produce self-excitation. The occurrence of the instability has been interpreted as due to adverse changes in the structural mass, damping, and fluid-structure coupling force (Ref. 88). However, most of the expressions for predicting the onset of instability are based on compilations of direct measurements of the critical velocities at the onset of instability.

(f) *Cross flow* is a flow perpendicular to the structural longitudinal axis. Cross flow is one example where an FIV mechanism is produced that can create either a weakly or a strongly coupled fluid-structure system. Vortex shedding in the wake of a tube in cross flow produces both fluid excitation forces and fluid-structure coupling forces that amplify structural motion. For ideal cross flow, where a long, smooth surface tube is isolated in uniform (2-D) cross flow with little or no turbulence in the approaching flow stream, very periodic, two-dimensional vortices are shed. These vortices

produce alternating lift forces normal to the tube axis and flow and are nearly as large as the steady, flow direction drag forces, if the Reynolds number, based on the tube diameter, is below 2×10^5 (Refs. 82, 87, and 89). If the vortex shedding frequency is sufficiently different from the structural natural frequencies, the alternating lift forces act as fluid excitation forces only. However, if the vortex shedding frequency and one of the structural natural frequencies are sufficiently close to each other and the fluid excitation forces can produce large enough motion, then coupled fluid-structure forces occur, which apparently further amplify the motion. Enough experimental data are available to bound the fluid excitation forces, but the representation of the coupled fluid structure forces is still being researched. Most of the representations are based on highly phenomenological models that stimulate, to various degrees, a small amount of data covering only a narrow range of idealized conditions.

(g) The *joint acceptance* is a measure of the probability that a structure vibrating in one mode will remain in the same mode when excited by a random force; the *cross acceptance* is a measure of the probability that a structure vibrating in one mode will change to another mode when excited by a random force. For many applications only the joint acceptance is assumed to be important. When mode shapes are normalized to unity, the sum of the joint acceptances is equal to 1

Page 392

(see N-1342.1). Therefore, the assumption that the joint acceptance is equal to 1 gives conservative estimates of structural responses.

N-1312 Nomenclature

C_n = reduced damping in n th mode
 C_L = lift coefficient
 D = cylinder diameter
 E = Young's modulus
 f_n = natural frequency of n th vibration mode, hertz
 f_s = frequency of periodic vortex shedding, hertz
 F = force
 G_f = single-sided power spectral density of the forcing function, in (force/length)² per Hz
 G_i^f = G_f spectrum for the i th span of a multi-span tube
 G_y = single-sided power spectral density of response
 H_j = transfer function of j th vibration mode
 I = area moment of inertia
 J^2 = joint acceptance
 J_{jk}^2 = cross acceptance for the j th and k th vibration modes
 $(J_{jk}^i)^2$ = acceptance for the i th span
 ℓ_c = axial correlation length
 $= 2 \int_0^{\ell_c} r(x') dx'$ where $r(x')$ is the correlation function and x' is the separation distance
 ℓ_c^i = correlation length in the i th span
 L_e = cylinder length subject to vortex shedding
 L_i = span length
 m = mass per unit length
 m_A = added fluid mass per unit length
 m_c = contained fluid mass per unit length
 m_f = cylinder displaced fluid mass/length
 m_s = structural mass per unit length
 m_t = total mass per unit length of tube
 $= m_A + m_c + m_s$
 M_j = modal mass
 M_n = effective modal mass/length for n th vibration mode
 n = vibration mode, $n = 1$ is fundamental mode
 p = pressure
 P = tube pitch
 $=$ distance between tube centers
 q = dynamic pressure, $(1/2)\rho V^2$

FIG. N-1321-1 VORTICES SHED FROM A CIRCULAR CYLINDER

FIG. N-1321-1 VORTICES SHED FROM A CIRCULAR CYLINDER

N-1320 VORTEX SHEDDING

N-1321 Vortex Shedding From a Fixed Bluff Body

For a bluff body in uniform cross flow, the wake behind the body is no longer regular, but contains distinct vortices of the pattern shown in Fig. N-1321-1 for a circular cylinder. The vortices are shed alternatively from each side of the body in a regular manner and give rise to an alternating lift force. Experimental studies of this vortex shedding process have shown (Refs. 94 and 95) that the frequency in hertz of the alternating lift force can be expressed as:

$$(68)f_s = SV/D$$

Some common types of bodies or structures for which vortex shedding occurs are shown in Fig. N-1321-2. The following discussions are based on the circular

Page 393

cylinder; however, the concepts apply equally well to other bluff bodies.

FIG. N-1321-2 SOME TYPICAL CROSS SECTIONS OF BLUFF BODIES THAT CAN EXPERIENCE VORTEX SHEDDING

FIG. N-1321-2 SOME TYPICAL CROSS SECTIONS OF BLUFF BODIES THAT CAN EXPERIENCE VORTEX SHEDDING

The oscillating lift force produced on an isolated single cylinder of diameter D and length L by uniform cross flow can be expressed as (Refs. 96 and 97):

$$(69) F = C_L J q D L [\sin (2\pi f_s t)]$$

where C_L , f_s , and J are functions of the Reynolds number Re and must be determined experimentally. In uniform cross flow, the energy of vortex shedding occurs over a very narrow frequency band with a center frequency f_s except over a transition band of Reynolds number (2×10^5 to 3×10^6) where the character of the frequency content may vary from almost periodic to completely random. The measured Strouhal number is $SB 0.2$ for $10^3 < Re < 2 \times 10^5$; for larger Re , experimental values of S and C_L show considerable scatter.

The alternating vortex fluid forces are not generally correlated over the entire cylinder length L . As a consequence, two limiting cases of the joint acceptance exist for a uniform rigid-body-mode (Ref. 97).

$$\begin{aligned} J^2 &= \ell_c / L && \text{if } \ell_c \ll L \\ &= 1 && \text{if fully correlated} \end{aligned} \quad (70)$$

(70)

The correlation length in the lift direction for stationary cylinders has been found to be approximately 3 to 7 diameters ($3D < \ell_c < 7D$), for $10^3 < Re < 2 \times 10^5$ (Ref. 87). For larger Reynolds numbers, the correlation lengths for stationary cylinders can be expected to be even smaller because the attached boundary layer becomes fully turbulent. J^2 is usually much less than 1 for long stationary cylinders. Motion of the cylinder at the frequency of vortex shedding substantially increases the correlation length (Refs. 82 and 87) as discussed in N-1323 and N-1324.

Vortex shedding also induces a force in the stream-wise or drag direction. The drag force occurs at twice the vortex shedding frequency for single cylinders (Ref. 87). However, the magnitude of the oscillating drag force is typically an order of magnitude smaller than the oscillating lift force.

N-1322 Practical Cross Flow

The case of ideal cross flow is rarely found except in the laboratory. Many practical conditions reduce the effectiveness and strength of vortex shedding as an excitation mechanism:

(a) If the body is located in a turbulent flow, or if the tube surface is rough, the turbulence tends to widen the band of shedding frequencies and decrease the energy at the dominant shedding frequency (Ref. 129).

(b) If the cylinder is inclined to the flow, the shedding frequency can be adequately predicted by employing the component of flow velocity normal to the cylinder axis

$$(71) f_s = (SV/D) \cos \theta$$

where θ is the angle between the direction of flow and the normal to the cylinder axis. Inclined flow tends to reduce the magnitude of the vortex shedding forces (Ref. 98).

(c) Spanwise variations in flow velocity imply that the vortex shedding frequency also varies in the spanwise direction. This effect will generally reduce the magnitude of the net vortex shedding excitation.

(d) There is some evidence (Refs. 99, 100) that vortex shedding does not occur in two-phase flow and that vortex shedding is only a concern in single-phase flows.

(e) While the vortex shedding characteristics discussed above have general applicability, the effects of adjacent bodies have not been specifically included. Studies of two (Ref. 101) or more circular cylinders show that vortex shedding does occur, but its character is very sensitive to the relative location and spacing of the cylinders. For the important case of tube arrays, the values of S , J , and C_L to be employed in Eq. (69) of N-1321 are much more uncertain than for single cylinders, as is evident by the considerable scatter in the experimental data (Refs. 100, 102, 103, 104, 105, 139, and 140).

N-1323 Flexible Cylinders

When the vortex shedding frequency f_s is sufficiently different from the structural natural frequencies, a condition called off-resonance, the representation of the vortex shedding lift force by F given in Eq. (69) of N-1321 is valid, and is conservative if $C_L = 1$ and $J = 1$ is chosen. This conservative representation of the force can be extended to nonuniform loading, and modal response can be employed to simplify the analysis of cylinders where many modes are active. Normally, off-resonance response is small. However, as resonance is approached, large motions are encountered.

In the case of a single flexible or resiliently supported tube, once vibration begins the shedding frequency and the tube natural frequency can become synchronized if the two are sufficiently close. For a spring-supported cylinder in an air stream, it was shown (Ref. 106) that the velocity range over which synchronization persists depends upon the damping parameter, $m_t \delta_t / \rho D^2$. In Fig. N-1323-1, the shaded area is the region of synchronization. The ordinate, $V/f_n D$, is a reduced velocity, where f_n is the natural frequency of the spring-mounted cylinder. Note, in particular, that with increasing $m_t \delta_t / \rho D^2$ the reduced velocity range over which synchronization persists decreases, and no synchronization occurs for $m_t \delta_t / \rho D^2 < 32$. Outside the shaded area, the cylinder experiences an alternating lift force at the vortex shedding frequency for a stationary cylinder, as given previously in Eq. (69) of N-1321.

The consequences of synchronization are many. As the flow velocity is either increased or decreased so that the vortex shedding frequency approaches the structure frequency, the following will occur.

(a) The vortex shedding frequency shifts to the structural natural frequency, i.e., it synchronizes with or "locks-in" to the structural frequency even if the flow velocity or the structural frequency is varied within the range of synchronization as indicated in Fig. N-1323-1.

(b) The spanwise correlation of the vortex shedding forcing function increases rapidly as structural response increases.

(c) The lift force becomes a function of structural amplitude.

(d) The drag force on the structure increases.

(e) The strength of the shed vortices increases.

Within the synchronization band, substantial resonant vibration in lightly damped structures often occurs. Vibration amplitudes up to three diameters peak-to-peak have been observed in dense fluids, such as water, over cables and tubing. The vibrations are predominantly transverse to the flow and they are self-limiting (Refs. 82, 87, and 94).

Large-amplitude, synchronized vibrations in the drag direction have been observed for a single cylinder in water. These oscillations initiate at relatively low flow velocities corresponding to subharmonic frequencies of vortex shedding, i.e., at $1/4$, $1/3$, or $1/2$ the flow velocity required for synchronization according to Eq. (68) of N-1321 (Refs. 107 and 108). However, the synchronization in the drag direction is not as strong as in the lift direction, and usually occurs only for lightly damped structures in dense fluids (Refs. 87 and 110). Lock-in has not been observed in two-phase flow or deep (more than a few rows) inside a closely spaced tube bundle.

N-1324 Design Procedures for a Circular Cylinder

Whenever possible, lock-in operating conditions should be avoided, but complex designs often make this impossible. Thus, criteria are given for which lock-in can be avoided, and off-resonance structural dynamic analysis can be employed, as well as design procedures to calculate the response during lock-in.

N-1324.1 Avoiding Lock-In Synchronization.

Lock-in for a single cylinder can be avoided by one of the following four methods (Refs. 82, 106, 108, and 109). For tube arrays, only (a), (b), and (c) are applicable methods, and V must be the flow velocity in the minimum gap (P - D).

(a) If the reduced velocity for the fundamental vibration mode ($n = 1$) satisfies:

$$(72) V/f_n D < 1$$

then both lift and drag direction lock-in are avoided.

Page 395

FIG. N-1323-1 SYNCHRONIZATION OF THE VORTEX SHEDDING FREQUENCY AND THE TUBE NATURAL FREQUENCY FOR A SINGLE, FLEXIBLY-MOUNTED CIRCULAR CYLINDER. SYNCHRONIZATION OCCURS WITHIN THE SHADED REGION. (REF. 106)

FIG. N-1323-1 SYNCHRONIZATION OF THE VORTEX SHEDDING FREQUENCY AND THE TUBE NATURAL FREQUENCY FOR A SINGLE, FLEXIBLY-MOUNTED CIRCULAR CYLINDER. SYNCHRONIZATION OCCURS WITHIN THE SHADED REGION. (REF. 106)

(b) If for a given vibration mode the reduced damping is large enough

$$(73) C > 64$$

then lock-in will be suppressed in that vibration mode.ⁿ

(c) If for a given vibration mode

$$(74) V/f_n D < 3.3$$

and

$$(75) C_n > 1.2$$

then lift direction lock-in is avoided and drag direction lock-in is suppressed.

(d) If the structural natural frequency falls in the ranges $f_n < 0.7f_s$ or $f_n > 1.3f_s$ then lock-in in the lift direction is avoided in the n th mode.

The reduced damping C_n is calculated according to

$$C_n = \frac{4\pi\xi_n M_n}{\rho D^2 \int_{L_e} \phi_n^2(x) dx} \quad (76)$$

(76)

where $\xi_n = \delta_n/2\pi$ is the fraction of critical damping measured in air and M_n is the generalized mass

$$M_n = \int_0^L m(t) \phi_n^2(x) dx \quad (77)$$

(77) with ϕ_n the n th mode shape function and $m_t(x)$ is the cylinder mass per unit length. The range L_e in the denominator implies that the integration is over only the region of the cylinder length subject to lock-in cross flow. Note that m_p is calculated according to:

$$(78) m_t(x) = m_s(x) + m_c(x) + m_A(x)$$

For an isolated cylinder, m_A is the displaced fluid mass. If sections of the cylinder are close to other bodies, then the possibility of increased added mass and fluid damping must be taken into account (Refs. 81, 82, 90 to 93).

N-1324.2 Vortex-Induced Response.

Off resonance, the response can be calculated using standard methods (Ref. 96) of forced-vibration analysis and Eq. (69) for the forcing function (Refs. 82 and 89). The resultant response is ordinarily small. If operating conditions are such that lock-in cannot be avoided or suppressed, then the resonant vortex induced response must be calculated. Three approaches for calculating the response are recommended for three classes of structures and flows: single uniform cylinder in uniform flow, tube arrays, and nonuniform cylinders in nonuniform flow.

(a) *Uniform Structure and Flow.* If a uniform cylinder is subject to uniform cross flow over its span, then both the vortex shedding frequency and the vortex force are constant over the span of the cylinder. The periodic vortex induced lift force is given by Eq. (69) of N-1321. At lock-in, the vortex shedding frequency equals the natural frequency of the n th vibration mode, $f_s = f_n$ and the cylinder response is given by (Refs. 82 and 89)

$$\frac{y_n^*}{D} = \frac{C_L J \phi_n^*}{16 \pi^2 S^2 [m_i \xi_n / (\rho D^2)]} \quad (79)$$

(79)

This equation provides a conservative upper bound estimate to the amplitude of periodic vortex-induced vibration if the lift coefficient is taken as unity, $C_L = 1$, and the vortex shedding is fully correlated along the span of the cylinder, $J = 1$. Other values of C_L and J may be used in circumstances where experimental data are available. However, Eq. (79) with $C_L = 1$ and $J = 1$ has been found to give overly conservative predictions owing to the tendency of the actual lift coefficient to decrease at vibration amplitudes exceeding 0.5 diameter and the lack of perfect spanwise correlation at lower amplitudes. To obtain less conservative predictions, three semiempirical nonlinear methods are given in Table N-1324.2(a)-1. The mode shape factor γ generally varies between 1.0 and 1.3 (Ref. 82) and C_n is determined according to Eq. (76) of N-1324.1 using ξ_n determined in air.

(b) *Within Tube Arrays.* Coherent vortex shedding has been found to exist only in the first few rows in arrays of cylinders with center-to-center spacing less than 2 diameters, and the design procedures for a single cylinder are applicable using the velocity in the minimum gap ($P-D$). Within the array vortex shedding exists over a broad range of frequencies rather than at a single distinct frequency. The response within the array is generally less than that of a comparable single cylinder. The techniques that have been developed to predict vibration within the array are based on the theory of random vibration and are given in N-1340.

82	$\frac{y_n^*}{D} = \frac{0.07\gamma}{(C_n + 1.9)S^2} \left[0.3 + \frac{0.2}{(C_n + 1.9)S} \right]^{1/2}$
110	$\frac{y_n^*}{D} = \frac{0.32}{[0.06 + (2\pi S^2 C_n)^2]^{1/2}}$

TABLE N-1324.2(a)-1 SEMIEMPIRICAL CORRELATIONS FOR PREDICTING RESONANT VORTEX-INDUCED VIBRATION AMPLITUDE

(c) *Nonuniform Structures and Flow.* Many cylindrical structures have nonuniform distribution of mass and stiffness, and they are exposed to flow velocities that vary over the span. In this case, only a part of the span of structure will resonate with vortex shedding and contribute to the excitation.

One method for treating nonuniform structures in nonuniform flows is:

- (1) determine the natural frequencies and mode shapes of the structure;
- (2) determine the spanwise distribution of the flow;

(3) identify portions of the structure that can resonate with vortex shedding for each mode. This can be done by calculating the spanwise distribution of the vortex shedding frequency and estimating the potential for resonance by a band of plus or minus 30% from this frequency.

(4) Apply a lift force given by Eq. (69) of N-1321 with $f_n = f_s$ and $C_L = 1$ to those segments of the span that are resonant.

Procedures (1) through (4) are illustrated in Refs. 89 and 112. For a uniform cylinder in uniform cross flow, assumption (4) of complete correlation and $C_L = 1$ gives overly conservative predictions. Other values

Page 397

for C_L may be used where experimental data are available.

N-1330 FLUID-ELASTIC INSTABILITY

Many FIV mechanisms exist wherein as energy supplied to the system is increased, usually as increased flow velocity, a critical value is attained at which a large increase in response occurs. Continued increases in the supplied energy results in continued static or dynamic divergences (rapid increases) of the response. In general, fluid-elastic instability is a result of strong coupling between the structure and the fluid.

N-1331 Instability of Tube Arrays in Cross Flow

Fluid flow across an array of elastic tubes can induce a dynamic instability that can result in very large amplitude vibrations once a critical cross flow velocity is exceeded. Often, motion is limited only by tube-to-tube impacting. The flow of fluid over the tubes results in both fluid excitation and fluid-structure coupling forces on the tubes. The fluid-structure coupling excitation forces fall into several groups:

(a) forces that vary approximately linearly with displacement of a tube from its equilibrium position (displacement mechanisms) (Ref. 113);

(b) fluctuations in the net drag forces induced by the oscillating tube's relative velocity with respect to the mean flow (fluid damping mechanism) (Ref. 88); and

(c) combinations of the above forces that exhibit step changes as a certain amplitude is exceeded because of the abrupt shift in the point of flow separation (jet switch mechanism) (Ref. 114). Instability may result from any or all of these fluid forces which are functions of the tube motion.

The general characteristics of tube vibration during instability are as follows.

(d) *Tube Vibration Amplitude.* Once a critical cross flow velocity is exceeded, vibration amplitude increases very rapidly with flow velocity V , usually as V^n where $n = 4$ or more, compared with an exponent in the range $1.5 \leq n \leq 2.5$ below the instability threshold. This can be seen in Fig. N-1331-1, which shows the response of an array of metallic tubes to water flow. The initial hump is attributable to vortex shedding that tends to produce larger amplitudes in water flow than air flows.

(e) *Vibration Behavior With Time.* Often the large amplitude vibrations are not steady in time, but rather beat with amplitudes rising and falling about a mean value in a pseudorandom fashion (Ref. 115).

(f) *Synchronization Between Tubes.* Most often the tubes do not move as individuals, but rather move with neighboring tubes in somewhat synchronized orbits, as shown in Fig. N-1331-2. This behavior has been observed in tests both in water and air (Refs. 113, 115, 116, and 117), with orbit shapes ranging from near circles to near straight lines. As the tubes whirl in their oval orbits they extract energy from the fluid. The stiffness mechanism requires motion of the adjacent tubes, but the damping mechanism does not.

(g) *Influence of Structural Variations.* Restricting the motion or introducing frequency differences between one or more tubes often increases the critical velocity for instability (Refs. 115, 116, and 118). Such increases are generally no greater than about 40%. Often the onset of instability is more gradual in a tube bank with tube-to-tube frequency differences than in a bank with identical tubes which are free to vibrate.

N-1331.1 Prediction of the Critical Velocity.

Dimensional analysis considerations imply that the onset of instability is governed by the following dimensionless groups: the mass ratio $m/\rho D^2$; the reduced velocity V/fD ; the damping ratio ξ_p , measured in the fluid; the pitch to

diameter ratio P/D ; the array geometry (see Fig. N-1331-3), and the Reynolds number VD/ν . In this section, V is the flow velocity in the gaps between the tubes, and is determined by the product of $P/(P-D)$ and the (approach) flow velocity that would occur if the tubes were not present. Note the added mass part of m_t may be much larger than the displaced fluid mass because of the confining effect of adjacent tubes (Refs. 81, 90, and 92). Also, for most cases, the flow is fully turbulent ($VD/\nu > 2000$) and the Reynolds number is not expected to play a major role in the instability. In such cases, the reduced critical velocity for the onset of instability can be expressed as a function of the remaining nondimensional parameters.

The relationship between the parameters can be investigated theoretically or experimentally. One general form that has been used to fit experimental data is:

$$(80) V_c/f_n D = C (m_t/\rho D^2)^a (2\pi\xi_n)^b$$

where C and the indices a and b are functions of the tube array geometry. Experimental data suggest that a and b fall in the range $0.0 < a, b < 1.0$ (Refs. 115, 116, 119, 138, and 139).

N-1331.2 Recommended Formula.

Mean values for the onset of instability can be established by fitting

Page 398

semiempirical correlations to experimental data. The correlation form chosen is

$$(81) V_c/f_n D = C [m_t (2\pi\xi_n)/\rho_{gr} D^2]^a$$

FIG. N-1331-1 RESPONSE OF A TUBE BANK TO CROSS FLOW (REF. 115)

FIG. N-1331-1 RESPONSE OF A TUBE BANK TO CROSS FLOW (REF. 115)

FIG. N-1331-2 TUBE VIBRATION PATTERNS AT FLUIDELASTIC INSTABILITY FOR A FOUR-TUBE ROW (REF. 118)

FIG. N-1331-2 TUBE VIBRATION PATTERNS AT FLUIDELASTIC INSTABILITY FOR A FOUR-TUBE ROW (REF. 118)

where,

U_c

= critical cross flow velocity

f_n

= natural frequencies of the immersed tube For uniform cross flow, the tubes will be stable if the representative cross flow velocity V is less than the critical velocity V_c . If the flow is nonuniform over the tube lengths, an equivalent uniform cross flow gap velocity can be defined as either the maximum cross flow velocity, or the modal weighted velocity:

$$V_e^2 = \int_0^L V^2(x) \phi_n^2(x) dx / \int_0^L \phi_n^2(x) dx \quad (82)$$

(82)

where $V(x)$ is the cross flow velocity at each axial location of the tube. The tubes will be stable if $V_e < V_c$ for all modes.

The available 170 data points for onset of instability (Ref. 120) are shown in Fig. N-1331-4. In the range $m(2\pi\xi_\eta)/\rho D^2 >$

0.7, there are sufficient data to permit fitting of Eq. (81) to data for each array type. The mean values of C are

	Triangle	Rotated Triangle	Rotated Square	Square	All
C_{mean}	4.5	4.0	5.8	3.4	4.0

Based on theory for the displacement mechanism (Ref. 113), which is active in this parameter range, $a = 0.5$ was chosen in these fits. For $m(2\pi\xi_n)/\rho D^2 < 0.7$, where the fluid damping mechanism is primarily active, neither the theory nor data are sufficient to establish values of C and a in Eq. (81). Conservative estimates of the mean values of $V_{\infty} f_n D$ for $m(2\pi\xi_n)/\rho D^2 < 0.7$ can be obtained using Eq. (81) with $a = 0.5$ and the mean C given in the table above. The use of Eq. (81) with $a = 0.5$ and $C = 3.3$ has been recommended (Refs. 80, 100) for the entire mass damping parameter range of Fig. N-1331-4.

N-1331.3 Suggested Inputs.

Accurately predicting the critical velocity requires scale model testing to determine the value of C and the damping ratio in each application, because practical flow and structural geometries contain features nonexistent in the simpler, controlled laboratory tests used to establish the data base of Fig. N-1331-4 (Ref. 120). Usually, industrial tube arrays (bundles) involve multiple spans with intermediate supports provided by plates with holes slightly larger than the tube diameter. Also, flow may pass

around the edge of the bundle and does not have the pure cross flow direction shown in Fig. N-1331-3, even within the bundle. Furthermore, when the vibration amplitude is small, such as that experienced during subcritical vibration, not all support plates are active. Damping ratios in this vibration mode are typically small, from 0.1% in gas to about 1% in steam or water. When the vibration amplitude is large, as characterized by the onset of instability, support plate-to-tube interaction greatly increases the damping ratio which can reach 5% or more.

FIG. N-1331-3 TUBE ARRANGEMENTS

FIG. N-1331-3 TUBE ARRANGEMENTS

FIG. N-1331-4 STABILITY DIAGRAM

FIG. N-1331-4 STABILITY DIAGRAM

All the practical features discussed above tend to raise the critical flow velocity. Thus, the data base of Fig. N-1331-4 can be used to determine a conservative criterion for avoiding fluid-elastic instabilities of tube arrays: if the design equivalent uniform cross flow gap velocity [Eq. (82)] is less than the critical velocity [Eq. (81)] computed with the suggested design values defined by the solid line ($C = 2.4$, $a = 0.5$) in Fig. N-1331-4 and with a damping ratio of 0.5% in gas, or 1.5% in "wet" steam or liquid, then instability is almost certainly not a problem, and scale model testing will not be necessary. Otherwise, more accurate values of C and the immersed tube's damping ratios, or the critical velocity itself, must be determined by either model testing or from operational experience.

N-1340 TURBULENCE

In general, the coolant flow paths and flow rates promote and maintain turbulent flows that are optimal for purposes of heat transfer, but provide sources for structural excitation. Also, turbulence in the flow can affect the existence and strength of other excitation mechanisms associated with separating boundary layer flows (wakes), as discussed in N-1320 on vortex shedding. This section will concentrate on turbulence as a source of fluid excitation forces.

N-1341 Random Excitation

Where turbulent flow comes into contact with the surface of a structure some of the momentum in the flow is converted into fluctuating pressures. In addition to any forces produced by the mean flow component, random surface pressure fluctuations are produced by the turbulent velocity component. The time history of the surface pressure fluctuations, like the flow turbulence, is complex and amenable to description only on a statistical basis. However, the fluctuating pressure and the resulting flow-induced response usually can be regarded as ergodic and analyzed with a finite-time record not dependent upon the time origin.

For purposes of structural analysis and design, most useful information on the fluctuating pressures becomes available once the spatial spectral densities of the pressure field, $S_p(x_1, x_2, \Omega)$, are determined. The spectral density is the Fourier transform of the cross correlation of the pressure field

$$S_p(x_1, x_2, \Omega) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \left\{ \lim_{t_0 \rightarrow \infty} \frac{1}{2t_0} \int_{t_0}^{t_0+t} p(x_1, t) \right. \quad (83) \\ \left. \times p(x_2, t + \tau) d\tau \right\} e^{-i\Omega t} dt$$

(83) and provides information about the average products of components of the pressure $p(x, t)$ as a function of the circular frequency Ω in radian/sec for every possible pairing of structural points, x_1 , and x_2 , including the same point. S_p has units of (pressure)² (second). The frequency content of the spectra are band limited, from zero to a maximum frequency determined by the turbulence source. The magnitude of the power spectra increases when the energy of the turbulence at frequency Ω increases. The size of a region of the structure over which the pressures at different points are coherent, or has some cause-effect relationship, is interpreted as a correlation length of the pressure field, or the size of the associated turbulent eddy (Ref. 82).

Only select parts of the surface pressures are effective in exciting dynamic structural response: those parts with frequency content in narrow bands centered on the structural natural frequencies and with correlation lengths similar in size to the spatial wavelength of the associated vibration mode (Ref. 122). The resulting structural response occurs in the

narrow frequency bands with random amplitudes, and the widths of the frequency bands are determined by the system damping. Knowledge of the surface pressure statistics enables prediction of the associated structural response statistics utilizing the probabilistic theory of structural dynamics.

N-1342 Structural Response of Tubes and Beams

N-1342.1 Response to Homogeneous Turbulence Excitation.

The assumption of a linear structure is justifiable for the small vibrations associated with the turbulence excitation of weakly coupled fluid-structure systems, and the linear structural dynamic analysis theory for arbitrary random loading of beams is highly developed. Since the energy dissipation mechanism of turbulent flow rapidly smooths disturbances caused by

Page 403

the structural boundaries of and in the flow channel, the statistical character of turbulent cross flow often varies gradually over the total length of select spans of single tubes and tube bundles, especially within the bundles. Thus, in many applications, the assumption of a uniform mean velocity and homogeneous turbulence is reasonable.

Assuming a homogeneous and ergodic pressure field, the equations of motion can be uncoupled to allow solution by modal analysis (see N-1222). The expression for the power spectral density of the cylinder response is (Ref. 123)

$$S_y(x_1, x_2, \Omega) = S_{fo} L_j^3 \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} \phi_j \phi_k J_{jk}^2 H_j H_k^* \quad (84)$$

(84)

The mode shapes $\phi_j(x)$ satisfy the orthogonality relation

$$\int_0^L m_t(x) \phi_i(x) \phi_j(x) dx = M_j \delta_{ij} \quad (85)$$

(85)

where M_j is the generalized mass, defined here to have the same dimensions as m_t . Thus, if m_p is constant, $M_j = m_t$ and the orthogonality condition reduces to

$$\int_0^L \phi_i(x) \phi_j(x) dx = \delta_{ij} \quad (86)$$

(86)

The transfer function for the j th mode is

$$H_j(\Omega) = [M_j(\Omega_j^2 - \Omega^2 + 2i\xi_j\Omega\Omega_j)]^{-1} \quad (87)$$

(87) where Ω_j and ξ_j are the modal natural frequency and damping, respectively. The acceptance integral is

$$J_{jk}^2(\Omega) = L^{-1} \int_0^L \int_0^L \phi_j(x_1) \Gamma(x_1, x_2, \Omega) \phi_k(x_2) dx_1 dx_2 \quad (88)$$

(88) where the complex coherence function is

$$(89) \Gamma(x_1, x_2, \Omega) = S_f(x_1, x_2, \Omega) / S_{f0}(\Omega)$$

and S_f is the cross spectral density of the turbulent forcing function per unit length between two different points on the cylinder's length, $x = x_1$ and $x = x_2$. When $x_1 = x_2 = x$, $S_f(x, x, \Omega) = S_{f0}(\Omega)$ is the power spectral density (or auto spectrum) that is independent of location for a homogeneous pressure field. The joint acceptance $J_{jj}(\Omega)$ reflects the relative effectiveness of the forcing function to excite the j th vibration mode while the cross acceptance $J_{jk}(\Omega)$, $j \neq k$, reflects contributions due to coupling between different modes. In general, the responses in two different modes are dependent upon each other.

The mean square response $\bar{y}^2(X)$ is the most useful measure for the amplitude or stress and strain design, and is found by integration of the power spectral density of the response, $S_y(x, \Omega) = S_y(x, x, \Omega)$ over the frequency band, or

$$\underline{y}^2(x) = \int_{-\infty}^{\infty} S_y(x, \Omega) d\Omega \quad (90)$$

(90) The distribution of the positive and negative peaks in displacement has been found for the fundamental mode of a rod in parallel flow to be Gaussian (Refs. 81, 82, and 124). Assuming a Gaussian fluctuating pressure distribution, a Rayleigh distribution is expected for the absolute amplitude of response (Refs. 82 and 125).

Based on physical reasoning and experimental data, the complex coherence function of the homogeneous turbulence pressure field for the tubes in cross flow has been characterized as (Refs. 122 and 126)

$$\begin{aligned} R(x_1, x_2, \Omega) = & \exp [-2|x_1 - x_2|/l_c] \\ & \times \exp [-i\Omega(x_1 - x_2) \sin \theta/U_c] \end{aligned} \quad (91)$$

(91)

where l_c is the correlation length, which is a measure of the coherence range of the turbulent pressure field; U_c is the convection velocity, or the velocity at which the turbulent eddies move with the flow; and θ is the angle between the direction of the flow and the normal to the axis of the tube. Note that $U_c/\sin \theta$ is the phase velocity of the pressure signal along the tube.

In the case of lightly damped structures with well-separated modes, cross modal contribution to the response can be ignored, and Eq. (90) can be analytically evaluated to be (Refs. 112 and 125):

$$-12\underline{y}^2(x) = \sum_j 2\pi\xi_j\Omega_j S_y(\Omega_j) = \sum_j \pi\xi_j f_j G_y(f_j) \quad (92)$$

(92)

In the second equality, the response is expressed in terms of the more commonly used engineering variables frequency f (in Hz) and the single-sided power spectral density G as a function of f , where

$$\begin{aligned}
 G(f) &= 4\pi S(\Omega) \quad \text{for } f = \Omega/2 > 0 \\
 &= 0 \quad \text{for } f < 0.
 \end{aligned} \tag{93}$$

(93)

Under the same assumption of light structural damping

Page 404

$$\underline{y}^2(x) = \sum_j \frac{LG_f(f_j) \phi_j^2(x)}{64 \pi^3 M_j^2 f_j^3 \xi_j} J_{jj}^2 \tag{94}$$

(94)

Where $G_f(f_j)$ is the single-sided power spectral density in (force/length)²/Hz generated by the turbulent pressure field at the natural frequency f_j of the j th vibration mode.

N-1343 Design Procedures for Tubes and Beams in Turbulent Cross Flow

In most situations, the component of turbulent flow normal to the axis of a cylinder is a more dominant excitation mechanism than the parallel component. The exception occurs when the flow direction is parallel or barely inclined to the cylinder axis. Thus, cross flow analysis using the component of flow normal to the cylinder should always be made, supplemented by the parallel flow analyses of N-1345 at small angles of inclination.

The theory in the subsections that follow can be applied to one-dimensional structures in general, but the specific information on the statistics of the pressure field must be limited to tubes (circular cylinders) until adequate information is available for other beam cross sections.

N-1343.1 Uniform Cross Flow.

In the simplest case of uniform cross flow over the entire length of a lightly damped, rigid cylinder with an evenly distributed total mass and spring supports at both ends, $\phi = L^{-1/2}$, $thgr_i = 0$ in Eq. (91), and the joint acceptance integral of Eq. (88), with $i = j = 1$, reduces to (Refs. 112 and 127)

$$J_{11}^2 \approx l_c/L, \quad l_c \ll L \quad (95)$$

(95)

The correlation length l_c in most cross flows over a tube (circular cylinder) is no more than three diameters (see N-1322). Also, although Eqs. (95) were derived for the fundamental mode of the transverse vibrations of a rigid, spring-supported cylinder, they can be used to estimate the joint acceptance of the fundamental mode of cylinders which are simply supported or clamped at both ends. Of course, in determining the RMS response with Eq. (94), the mode shapes corresponding to the actual boundary conditions and normalized according to Eq. (86) are used. For other boundary conditions and higher modes, the joint acceptance integral will have to be evaluated either numerically (most cases) or in closed form from Eq. (91). Since $J_{11}^2 \leq 1.0$, (Ref. 127), an upper bound response estimate can be found by setting all the $J_{jj} = 1.0$ in Eq. (94).

TEXT

The random characteristics of the forces exerted on the tubes by the turbulent flow must be obtained from tests. Two expressions for the power spectral density of the turbulent force per unit length on tubes in a tube array are:

$$G(f) = [C_R(f)\rho V_g^2 D/2]^2 \quad (\text{Ref. 100}) \quad (96)$$

(96)

and

$$G(f) = [C_L(f)\rho V_g^2 D/2]^2 (D/V_g) \quad (\text{Ref. 128}) \quad (97)$$

(97)

where the gap velocity V_g is related to the velocity upstream of the tubes, V_∞ , by

$$(98) V_g/V_\infty = P/(P-D)$$

The coefficient $C_R(f)$ in Eq. (96) has units of $\text{sec}^{-1/2}$ and is given in Fig. N-1343-1 as a function of the frequency f . Therefore, the application of Eq. (96) should be limited to the parameter range for which the data were taken, namely, high turbulent water flow (1 to 2 m/sec) entering closely spaced heat exchanger tubes of 12 to 19 mm in diameter. The decrease in $C_R(f)$ with penetration into the bundle is attributed to the highly turbulent inlet flow and possible vortex excitation observed in the first few tube rows. Data for the nondimensional lift coefficient $C_L(f)$ of Eq. (97) have not been obtained for as many tube array configurations (Refs. 141 and 142), but use of this alternative expression may predict less conservative responses (Ref. 142).

For an isolated tube in cross flow, which is not subject to conditions of lock-in vortex shedding (see N-1323), the power spectral density $G_f(f)$ and the correlation length are strong functions of the turbulence created in the incident flow stream by the upstream structures. Relatively small amounts of turbulence can cause significant reductions in the effectiveness of vortex shedding as an excitation mechanism, and all periodicity can be eliminated with sufficiently strong incident turbulence. For given turbulence intensities and scale lengths of the incident flow, $G_f(f)$ is available (Ref. 129) and the correlation length l , may be approximated by the scale length of the incident flow. In the absence of specific information about the incident flow, the random turbulence coefficient for the upstream tube in Fig. N-1343-1(a) can be used to estimate $G_f(f)$ for most isolated tubes in cross flow because of the wide variety of incident flow conditions contained in the data base. In the latter case, the velocity used in Eqs. (96) and (97) should be the free stream velocity of the flow.

FIG. N-1343-1 RANDOM EXCITATION COEFFICIENT FOR ARRAYS IN CROSS FLOW (REF. 100)

FIG. N-1343-1 RANDOM EXCITATION COEFFICIENT FOR ARRAYS IN CROSS FLOW (REF. 100)

If upstream structures produce well defined vortices, strong excitation mechanisms may be created on isolated cylinders more than twenty diameters downstream (Ref. 130). Such configurations should be avoided.

N-1343.2 Multiple Spans of Uniform Cross Flow.

In many applications, a cylinder is subject to one or more partial spans of uniform, but different, velocity and density cross flows that are uncorrelated with each other or with the flow over the remainder of the cylinder's length. These conditions often exist when baffles are used to channel different density flows in the interior of the pressure vessels (heat exchangers, reactors, etc.). The mean square response for such conditions can be determined by simple generalizations of the results given in N-1342.2 for homogeneous turbulence excitation.

Since the uniform cross flow over the span of length L_i is uncorrelated with the uniform cross flows over the other spans, $G_f J_{jj}^2$ in Eq. (94) can be calculated (Ref. 127) by summing the products of the locally defined spectra G_f^i and joint acceptances $(J_{jj}^i)^2$ over all

TEXT

the spans i over which there is significant cross flow. Thus, the mean square response becomes

TEXT

$$\bar{y}^2(x) \approx \sum_j \sum_i \frac{L_i G_f^i(f_j) \phi_j^2(x)}{64 \pi^3 M_j^2 f_j^3 \xi_j} (J_{jj}^i)^2 \quad (99)$$

(99)

where

$$G_f^i(f_j) = G_f(f_j) \int_0^{L_i} \phi_j^2(x) dx \quad (100)$$

(100)

$(J_{jj}^i)^2$ are determined with Eq. (88) using that part of ϕ_j , denoted by ϕ_j^i , that is active over the i th span with length L_i . As discussed in N-1343.1, if ϕ_j^i is similar to the fundamental mode shape of a one-span beam with simple or clamped supports at each end, then $(J_{jj}^i)^2 \approx \ell_c^i/L_i$. The correlation lengths inside a tube bundle are smaller than that for an isolated tube, being about 1–2 tube diameters. After specifying $G_f^i(f)$ and using Eqs. (96) and (97) for instance, the mean square response can be determined.

TEXT

Page 406

N-1343.3 Nonuniform Cross Flow.

In industrial heat exchangers, the cross flow velocities are seldom uniform over the entire length, or even one span of the tubes. While an average cross flow velocity can be used to estimate the force spectra in Eqs. (96), (97), and (98), when the velocity distribution is available, better estimates can be obtained by using mode shape-weighted power spectral densities similar to the generalized forces used in deterministic analysis (Ref 127):

$$G_f(f_j) = (D/2)^2 C_R^2(f_j) \int_0^L [\rho U^2(x)]^2 \phi_j^2(x) dx \quad (101)$$

(101) for a single-span tube of uniform mass density and

$$G_f^i(f_j) = (D/2)^2 C_R^2(f_j) \int_0^{L_i} [\rho_i U^2(x)]^2 \phi_j^2(x) dx \quad (102)$$

(102)

for a multi-span of spanwise uniform mass density. These estimates are not rigorously derivable, but they will lead to more accurate estimates of response, especially when the peaks in the velocity distributions are close to the antinodes of the vibration modes.

N-1344 Vortex-Induced Vibrations in a Tube Bundle

The existence of vortex shedding deep in a tube bundle is much less clearly defined than for a single cylinder. Experimental measurements involving tube bundles showed that even if a resonance peak exists in the dynamic pressure power spectral density, it is much broader and not as well defined as in the case of a single tube. Furthermore, these peaks are bounded by the pressure power spectral density given by Eq. (96). However, if lock-in vortex-induced vibration occurs in a particular span, the forcing function and the tube mode shape will be fully correlated and in-phase for that span. This means that the span joint acceptance, $J_{jj}^i = 1.0$. To be conservative, a lock-in vortex-induced vibration amplitude deep in a multi-span tube bundle can be calculated by substituting $J_{jj}^i = 1.0$ into Eq. (99), for all spans and all modes where lock-in cannot be avoided or suppressed according to N-1324.1.

TEXT

Classical vortex shedding does occur in the boundary tubes. For the first two to three rows of tubes in a tube bundle, vortex-induced vibration analysis following the procedure outlined in N-1320 is recommended.

N-1345 Cylinders in Axial Flow

Turbulence generally is a much weaker excitation mechanism in axial flow compared with cross flow, where the flow separates from the vibrating body. Also, axial flow is a source of flow damping which increases with flow rate (Refs. 81, 82, and 131). As a result, RMS vibration amplitudes of tubes in axial flow are typically only a few percent of the tube diameter.

The surface pressure fluctuations that excite a tube in axial flow are due to many sources: local turbulence created by the shear flow in the developing boundary layer; free stream turbulence created by upstream disturbances (grid supports, abrupt changes in channel size, elbows, valves, etc.) that quickly attenuate downstream of the disturbance; localized acoustic noise (waves); and system acoustic noise that can propagate long distances (Ref. 136). For pipes and single rods in annuli subject only to fully developed flow, relatively general experimental characterizations of the homogeneous pressure fields are possible (Ref. 131), because they depend only on the local channel geometry and the flow rates. However, general characterizations have not been developed that account for upstream disturbances and adjacent bodies, although many specific systems have been studied (Refs. 131 through 137). Evidently, accurate predictions can be made when the pressure field is characterized in the same system as the response is measured, but the predictions from system to system may vary by an order of magnitude for the same axial flow velocity. Because response is usually much easier to measure than the pressure fluctuations necessary to characterize a pressure field, especially a nonhomogeneous one, empirical correlations of response have been developed for important component geometries (Refs. 99 and 137). The component and prototype tests upon which the correlations are based include all component geometries and excitation sources. Of course, the use of these correlations must be limited to the type of components and parameter variations for which they were developed.

N-1345.1 Recommended Design Procedures

(a) When the characterization of the pressure field is available, then the response of the structure can be predicted by the general method outlined in N-1342. But, unlike cross flows, the convection velocity U_c is important and must be known in axial flow before the acceptance integral, Eqs. (88) and (91), can be evaluated. In axial flows, it is not generally true that the larger the correlation length, ϵ , the larger the response as in cross flows. Rather, the response is governed by the matching of the structural mode shape and the phase-coherence of the pressure field (Refs. 112 and 122), in addition to its power spectral density.

(b) Regardless of whether a pressure field characterization is available, the maximum amplitude of motion

Page 407

can be estimated to within an order of magnitude using the empirical correlation (Ref. 99)

$$\frac{y^*}{D} = \left[\frac{5 \times 10^{-4} K_N}{\alpha^4} \right] \left[\frac{u^{1.6} \epsilon^{1.8} Re^{0.25}}{1 + u^2} \right] \times \left[\frac{D_h}{D} \right]^{0.4} \left[\frac{\beta^{2/3}}{1 + 4\beta} \right] \quad (103)$$

(103) if the cylinder parameters are within the ranges covered by the correlation:

$$2.1 \times 10^{-3} \leq u^2 = m_A V^2 L^2 / (EI) \leq 8 \times 10^{-1}$$

$$26.8 \leq \epsilon = L/D \leq 58.7$$

$$2.6 \times 10^4 \leq Re = VD/\nu \leq 7 \times 10^5$$

$$4.9 \times 10^{-4} \leq \beta = m_A/m_t \leq 6.2 \times 10^{-1}$$

$$2.10 \leq \alpha^2 = \Omega_1 [m_t L^4 / EI]^{1/2} \leq 20.8$$

$$1 \leq K_n \leq 5$$

where K_n is a noise factor representing a departure from quiet, steady axial flows of $K_n = 1$. Commercial systems are expected to be bounded by $K_n = 5$. E is the modulus of elasticity, I is the beam area moment of inertia, and ν is the fluid kinematic viscosity.

N-1400 DYNAMICS OF COUPLED FLUID-SHELLS

N-1410 INTRODUCTION

It is well known that the motion of a solid in a heavy liquid is different from that in a vacuum. In the case of a sphere or a cylinder moving in an infinite fluid medium, for example, the presence of the fluid can be accounted for by simply adding to the physical mass of the solid, the mass of fluid it displaces. Hence the term added mass, or hydrodynamic mass, has been used to describe this solid-fluid interaction phenomenon. When the fluid is viscous, then in addition to an added mass, there is an apparent added damping, or hydrodynamic damping, due to the viscosity of the fluid.

In the case of thin cylindrical shells vibrating with fluids entrapped in-between, the effect of fluid-structure interaction is far more complicated. Data from preoperational tests of nuclear plants showed that the natural frequencies of the thermal shields of light water nuclear reactors were much lower than their corresponding values measured in-air. Since then, theoretical studies by Fritz and Kiss (Ref. 143), Horvay and Bowers (Ref. 144), Au-Yang (Refs. 93 and 145), Chen (Refs. 90 and 146), Krajcinovic (Ref. 147), and Levin and Milan (Ref. 148) conclusively showed that the coupling effect of narrow fluid gaps on thin cylindrical shells is much stronger than that of infinite fluid media. Their conclusions are supported by

laboratory tests (Refs. 90 and 149). A few review papers on this topic were written by Chen (Ref. 90), Brown (Ref. 150), and Au-Yang (Ref. 151).

This guide describes a simple method to account for the effect of fluid-structure interaction on the response of cylindrical shells coupled by fluid gaps, using the structural priority approach (Ref. 155). In this approach, the effect of fluid-structure interaction is completely accounted for by the "added mass" and the "added damping" terms. The principal advantage of this method is its simplicity. Once the added mass and the added damping terms are computed, the structural response analysis can be carried out by standard methods without any need to revise the computer programs either for calculating the structural response or for calculating fluid forcing function. On the other hand this method is based on linear dynamic theory in which the principal interest is to estimate low-frequency structural responses. The vibration amplitude of the structure must be small compared with the width of the fluid gaps in order that linear dynamic theory holds. Internal structures of commercial nuclear reactors such as the core support structure and the thermal shield are usually restricted by limiter blocks so that their motions are small compared with the fluid annular gap width. In flow-induced vibration, seismic and loss-of-coolant analyses of these components, usually only the responses of the lower few modes are of interest, and the methods described in this guide can be applied. Structural analyses involving large displacements or in which responses to the high frequency components of the forcing function cannot be ignored, or analyses in which the principal interest is to estimate the hydraulic forcing function rather than the structural responses, should not follow the methods described in this guide.

N-1420 NOMENCLATURE

a	= radius of inner cylinder or (when used as a subscript or superscript) pertaining to the inner cylinder
b	= radius of outer cylinder or (when used as a subscript or superscript) pertaining to the outer cylinder
	Page 408
c	= velocity of sound

MATRIX

ε	= α or $(2\alpha - 1)/2$ as defined in Eq. (108)
θ	= azimuthal coordinate
Θ	= mode shape function
λ	= defined in Eq. (115)
μ	= surface mass density of the shell
ν	= hysteretic damping factor; kinematic viscosity
ρ	= mass density of fluid
ϕ	= axial acoustic mode shape function
ψ	= axial cylinder mode shape function
ω	= angular frequency (rad/sec)

N-1430 FREE VIBRATION OF THIN CYLINDRICAL SHELL IN AIR

Figure N-1430-1 shows the vibration mode of a thin, finite cylindrical shell. Viewed from the ends, the vibration of the cylinder may consist of any number of waves distributed around the circumference. The number of circumferential waves is denoted by n , with $n = 1$ being the beam mode. Throughout this write-up, it is assumed that the circumferential mode shape is normalized to unity,

$$\int_0^{2\pi} \Theta^2(\theta) d\theta = 1 \quad (104)$$

(104)

When viewed from the side, the deformation of the cylinder consists of a number of waves distributed along the length of a generator. The number of half waves along a generator is denoted by $m, m = 1, 2, 3, \dots$ As shown in Fig. N-1430-1, the axial wave forms depend on the end conditions of the cylinder.

The equation of motion for the free vibration of the shell is,

$$(105) [\mu](\ddot{q}) + [K](q) = 0$$

Thus to determine the natural frequencies, one has first of all to calculate the modal stiffness matrix. In simple cases of cylinders with simply supported or clamped ends, simplified expressions for the stiffness matrix elements have been derived (Refs. 92 and 152), and the natural frequencies of the shell can be computed. There will be three roots for each set of K_{ip} corresponding to three natural frequencies for each set of m, n . Two of these frequencies are usually much higher than the third one. These are associated with vibrations predominantly in the axial and tangential directions. The lowest frequency, on the other hand, is associated with vibrations predominantly in the normal direction. This is the flexural mode and is usually the mode of interest in structural analysis.

N-1440 ACOUSTIC MODES OF A FLUID ANNULUS BONDED BY RIGID WALLS

The natural frequencies associated with the (α, β) th mode of the fluctuation pressure distribution

$$(106) p_{\alpha\beta} = R_{\alpha\beta}(r)\phi(x)\cos\beta\theta$$

inside the fluid annulus are given by the roots of the equation (Ref. 153),

Page 409

$$J'_\beta(x_\alpha a)Y'_\beta(x_\alpha b) = J'_\beta(x_\alpha b)Y'_\beta(x_\alpha a) \quad (107)$$

(107)

FIG. N-1430-1 VIBRATION FORMS FOR CIRCULAR CYLINDRICAL SHELLS

FIG. N-1430-1 VIBRATION FORMS FOR CIRCULAR CYLINDRICAL SHELLS

where J , Y are Bessel functions and,

$$x_\alpha^2 = (w/c)^2 - (\epsilon\pi/l)^2 > 0 \quad (108)$$

(108)

ϵ

= α if the fluid annulus has both pressure released ($p=0$) or both hard ($p=\max$) ends;

= $(2\alpha - 1)/2$ if one end is pressure released and the other end is hard.

Note that acoustic modes exist in the fluid annulus only if,

$$\omega/c < \epsilon\pi/l.$$

The frequency at which,

$$\omega/c < \epsilon\pi/l.$$

is known in acoustics as the coincidence frequency.

N-1441 Frequency Equation and Mode Shape for a Thin Fluid Annulus

For many applications, the fluid annulus is thin compared with its radius, so that the condition $(b - a)/a < 5$ is satisfied. Under this condition, the following approximate equation for the natural frequencies holds true for the plane wave mode (no radial node).

$$f_{\alpha\beta} (c/2\pi) [(\epsilon\pi/l)^2 + [2\beta/(a+b)]^2]^{1/2}$$

The second radial mode (with one radial node) usually has a lowest frequency much higher than that of the fundamental radial mode up to $\alpha = \beta = 5$. Thus, it can be ignored if only the lowest twenty or so acoustic modes are included in the analysis.

N-1450 FREE VIBRATION OF COUPLED FLUID-SHELL SYSTEMS

When the cylindrical shells bounding the fluid annulus are flexible, then not only are the motions of the shells coupled to the fluid, but they are coupled together by the fluid between them. It was shown that (Ref. 145) there is no cross circumferential model coupling between the fluid and a system of two coaxial, circular cylindrical shells. However, except in the rare case when both the cylinder and the fluid can be represented by the same mode shape function, as is the case of a simply supported cylinder vibrating in a fluid annulus with open ends, there will be coupling between the axial structural and acoustic modes (Refs. 93 and 145).

N-1451 The Hydrodynamic Mass Matrix

It was shown that for small motions of the shell, the pressure induced by the structure in the fluid is proportional to the normal component of the acceleration $\bar{w}$, of shell (Refs. 93, 145, and 155):

$$(109) \quad (p) = [H](\bar{W})$$

The "constant" of proportionality is commonly called the hydrodynamic mass or added mass matrix. In general, it is a full matrix, the element of which is dependent on the frequency. For two coaxial cylindrical shells coupled by a fluid gap, the hydrodynamic mass matrix elements are (Refs. 93 and 145),

$$\begin{aligned}
H_{mn}^{ab} &= \sum_{\alpha} C_{\alpha m}^a C_{\alpha n}^b h_{\alpha\alpha}^{ab}, & H_{mn}^a &= \sum_{\alpha} (C_{\alpha m}^a)^2 h_{\alpha\alpha}^a \\
H_{mn}^{ba} &= \sum_{\alpha} C_{\alpha m}^a C_{\alpha n}^b h_{\alpha\alpha}^{ba}, & H_{mn}^b &= \sum_{\alpha} (C_{\alpha m}^b)^2 h_{\alpha\alpha}^b \quad (110)
\end{aligned}$$

(110)

where $C_{\alpha m}^a$ for example, is the projection of the m th axial mode shape, ψ_m of cylinder a (the inner cylinder) onto the α th axial acoustic mode shape ϕ_{α} of the fluid annulus:

TEXT

$$C_{\alpha m}^a = \int_0^{\ell} \psi_m^a(x) \phi_{\alpha}(x) dx \quad (111)$$

(111)

C_{α}^b are similarly defined. h (and hence H) are in units of mass per unit area.

TEXT

The general expressions for the hydrodynamic mass which are valid for any boundary condition and any D/L ratio, are quite complicated, but still can easily be computed with the aid of a personal computer. In the following paragraphs, simplified expressions for computing h are given for several commonly encountered special cases.

N-1451.1

N-1451.1 Slender Cylinder Approximation.

When the conditions $|\varepsilon\pi a/c| \ll 1$ and $|\varepsilon\pi b/c| \ll 1$ are simultaneously satisfied, Ref. 145 shows that:

$$\begin{aligned} h_{\alpha n}^a &= (\rho a/n)(b^{2n} + a^{2n})/(b^{2n} - a^{2n}) \\ h_{\alpha n}^{ab} &= -(2\rho b/n)(a^n b^n)/(b^{2n} - a^{2n}) \\ h_{\alpha n}^b &= (\rho b/n)(b^{2n} + a^{2n})/(b^{2n} - a^{2n}) \\ h_{\alpha n}^{ba} &= -(2\rho a/n)(a^n b^n)/(b^{2n} - a^{2n}) \end{aligned} \quad (112)$$

(112)

Note that the h 's are independent of the axial acoustical wave number α in this case. From N-1452.1, the

Page 411

generalized hydrodynamic masses per unit length for the beam mode ($n = 1$) are,

$$\begin{aligned} \bar{H}^a &= \rho\pi a^2(b^2 + a^2)/(b^2 - a^2) \\ \bar{H}^{ab} &= \bar{H}^{ba} = -2\rho\pi a^2 b^2/(b^2 - a^2) \\ \bar{H}^b &= \rho\pi b^2(b^2 + a^2)/(b^2 - a^2) \end{aligned}$$

N-1451.2 The Ripple Approximation.

When the ratio $(b - a)/(b + a)$ is small, curvature effects become unimportant and the annular gap can be treated as a rectangular fluid region. In this case, the expressions for the hydrodynamic masses are greatly simplified to.

$$h_{an}^a = h_{an}^b = \rho[\lambda_{an} \tanh(\lambda_{an}d)]^{-1} \quad (113)$$

$$h_{an}^{ab} = h_{an}^{ba} = -\rho[\lambda_{an} \sinh(\lambda_{an}d)]^{-1} \quad (114)$$

(113 - 114)

where $d = b - a$ and,

$$\lambda_{an}^2 = (\epsilon\pi/\ell)^2 + [2n/(a + b)]^2 - (\omega/c)^2 \quad (115)$$

(115)

N-1451.3 Incompressible Fluid Assumption.

When $\omega \ll \epsilon\pi$, the term ω/c can be dropped from the argument of the Bessel function in Eq. (107), the resulting hydrodynamic masses are independent of frequency. Since this condition is satisfied when $c \rightarrow \infty$, it is called the incompressible fluid assumption. However, the incompressible fluid assumption must be used with caution for applications to large structures. For a structure 300 in. long, vibrating in water at 600°F (e.g., nuclear reactor internal components), the incompressible fluid assumption generally introduces errors in the hydrodynamic matrix elements of more than 10% for frequencies above 20 Hz. Thus, it should not be used in analyses involving rapid transients in which high frequency contributions to the response are significant.

N-1451.4 Single Beam ($n = 1$) in Narrow Annuli.

When a cylinder vibrates inside a stationary, rigid cylinder of slightly larger diameter, its added mass due to the water between the two cylinders can be estimated by a very simple equation (Ref. 143):

$$(116) M' = \rho a^2 / [(b - a)(1 + 12a^2/\ell^2)]$$

The above equation is valid only for the beam mode ($n = 1$) vibration. Figure N-1451-1 is a comparison between Eq. (116) and the exact solution and shows surprisingly good agreement between them as long as the fluid gap is small.

From N-1452.1, the generalized, or effective hydrodynamic mass per unit length of the cylinder is:

$$(117) \bar{H}^a = \rho \pi a^2 / [(b-a)(1 + 12a^2/\ell^2)]$$

N-1451.5 Single Cylinder Containing Fluid.

The case when there is only one cylinder containing a fluid is given by (Ref. 145):

$$\begin{aligned} h_{\alpha n} &= \rho I_n(x_\alpha a) / [x_\alpha I'_n(x_\alpha a)] \quad \text{for } f < c\epsilon/2\ell \\ &= \rho J_n(x_\alpha a) / [x_\alpha J'_n(x_\alpha a)] \quad \text{for } f > c\epsilon/2\ell \\ &= \rho a/n \quad \text{for } f = c\epsilon/2\ell \end{aligned} \quad (118)$$

(118)

where J_n, I_n are Bessel and modified Bessel functions of the first kind. From N-1452.1, for the beam mode ($n = 1$), the generalized hydrodynamic mass per unit length of the cylinder is,

$$\bar{H}_1 = \pi a h_{\alpha 1}$$

N-1451.6 Single Cylinder in Infinite Fluid.

The case where there is only one cylinder in an infinite fluid is given by

$$\begin{aligned} h_{\alpha n} &= -\rho K_n(x_\alpha a) / [x_\alpha K'_n(x_\alpha a)] \quad \text{for } f < c\epsilon/2\ell \\ &= -\rho Y_n(x_\alpha a) / [x_\alpha Y'_n(x_\alpha a)] \quad \text{for } f > c\epsilon/2\ell \\ &= \rho a/n \quad \text{for } f = c\epsilon/2\ell \end{aligned} \quad (119)$$

(119)

From N-1452.1, for the beam ($n = 1$) mode, the generalized hydrodynamic mass per unit length is,

$$\bar{H}_1 = \pi a h_{\alpha 1}$$

N-1452 Natural Frequencies of Coupled Fluid-Shells in Special Cases

Once the hydrodynamic mass matrix is computed, it can be input into finite element computer programs to calculate the natural frequencies of fluid coupled

shells. First, several special cases in which simplified method of analysis can be used will be considered.

GENERAL NOTE: h_s^∞ is the Fourier coefficient for the hydrodynamic mass surface mass density of an infinitely long cylinder.

FIG. N-1451-1 COMPARISON OF FRITZ AND KISS SOLUTION WITH EXACT SOLUTION

FIG. N-1451-1 COMPARISON OF FRITZ AND KISS SOLUTION WITH EXACT SOLUTION

N-1452.1 One-Axial Mode Approximation.

In many cases of practical importance, when the D/l ratio of the cylinders are not very small, only the first axial mode

is important in the dynamic analysis. Under these circumstances the frequencies of two coaxial cylindrical shells coupled by a fluid gap between them can be estimated by solving the following simplified coupled equations (Ref. 154)

$$\begin{aligned}
 (\mu^a + \bar{H}_{\text{ln}}^a)[(f_{\text{ln}}^a)^2 - f^2]w^a - f^2 \bar{H}_{\text{ln}}^{ab}w^b &= 0 \\
 -f^2 \bar{H}_{\text{ln}}^{ba}w^a + (\mu^b + \bar{H}_{\text{ln}}^b)[(f_{\text{ln}}^b)^2 - f^2]w^b &= 0 \quad (120)
 \end{aligned}$$

(120)

where $[\bar{H}]$ is the generalized hydrodynamic mass matrix with elements:

$$\begin{aligned}
 \bar{H}_{\text{ln}}^a &= (q^a)^T [H^a \delta_{33}] (q^a) [(q^a)^T (q^a)]^{-1} = H_{\text{ln}}^a / (1 + n^{-2}) \\
 \bar{H}_{\text{ln}}^b &= H_{\text{ln}}^b / (1 + n^{-2}) \\
 \bar{H}_{\text{ln}}^{ab} &= H_{\text{ln}}^{ab} / (1 + n^{-2}) \quad (121)
 \end{aligned}$$

(121)

$\bar{H}_{ln}^a$, for example, is the generalized hydrodynamic mass of the inner cylindrical shell, expressed in terms of the hydrodynamic mass defined in Eq. (110). From Eq. (121) it can be seen that, because the hydrodynamic mass effects exist only in the normal direction, the effectiveness of H in reducing the natural frequencies of the shell is decreased by the factor $1 + n^{-2}$. For the beam mode ($n = 1$), its effectiveness is reduced by a factor of $1/2$. For high shell modes ($n \gg 1$), it is as effective as the physical mass.

TEXT

For each n , two coupled frequencies and amplitude ratios for w_a/w_b can be obtained by solving the system of Eq. (120). The torsional and longitudinal modes of vibration are not affected and are not coupled by the fluid gap in the inviscid fluid assumption. Note that $[H]$ is dependent on f and Eq. (120) has to be solved by iteration except in the incompressible fluid limit.

The above equations can be generalized to a system of several coaxial cylindrical shells coupled by fluid gaps between them (Ref. 155). However, since the hydrodynamic mass is frequency dependent, many iterations may be necessary to obtain all the coupled frequencies. This procedure may become prohibitive when there are more than three cylinders.

N-1452.2 Cases When Only One Cylinder is Flexible (Ref. 156).

If only one cylinder is flexible, coupling between cylinders can be ignored. The only parameter of interest is the "in-water" frequency of the shell, which is also the natural frequency of the fluid-shell system. In this case, the natural frequencies can be obtained by a graphical method. If one plots the two functions:

$$(122) g_1 = f f_{mn}$$

$$(123) g_2 = [1 + \bar{H}_{mn}(f)/m g r_s]^{-1/2}$$

then where g_1 and g_2 intercept is a natural frequency of the coupled fluid-shell system. The lowest coupled frequency is usually referred to as the "in-water" frequency of the shell while the higher coupled frequencies are usually referred to as acoustic frequencies. This distinction, however, has no technical basis.

In the incompressible fluid limit, only the "in-fluid" natural frequency of the cylinder is of interest. This is given by,

$$(124) f_{mn} = f_{mn} [1 + \bar{H}_{mn}/\mu]^{-1/2}$$

N-1453 Use of Hydrodynamic Mass Matrix in Finite Element Structural Computer Programs

Closed form solutions are possible only in highly idealized cases of perfect circular cylindrical shells with classical boundary conditions coupled by perfectly uniform annular gaps. In many applications, even though the fluid gaps are annular and the uncoupled fluid dynamic problem is amenable to closed form solution, closed form solutions to the

coupled fluid shell problem are not possible because the cylindrical shells are not uniform, and the boundary conditions are not classically simply supported or clamped. Examples of this sort are common in the nuclear industry. In these cases, the structural problem is usually solved with the help of finite element computer programs.

The effect of fluid-structure interaction can be readily incorporated into the finite element computer program using closed form solutions for the hydrodynamic mass matrix, provided that the finite element computer program is designed to accept a full mass matrix. Many commercially available finite element computer programs have this capability.

It was shown in Ref. 155 that in finite element form, the hydrodynamic mass matrix can be written as:

Page 414

$$[M_H] = \begin{bmatrix} a^{-1} \sum_{\alpha} h_{\alpha}^a (\phi_{\alpha} \Delta A^a) (\phi_{\alpha} \Delta A^a)^T & b^{-1} \sum_{\alpha} h_{\alpha}^{ab} (\phi_{\alpha} \Delta A^a) (\phi_{\alpha} \Delta A^b)^T \\ a^{-1} \sum_{\alpha} h_{\alpha}^{ba} (\phi_{\alpha} \Delta A^a) (\phi_{\alpha} \Delta A^a)^T & b^{-1} \sum_{\alpha} h_{\alpha}^b (\phi_{\alpha} \Delta A_b) (\phi_{\alpha} \Delta A_b)^T \end{bmatrix} \quad (125)$$

(125)

where $\Delta A^a, \Delta A^b$ are element surface areas. These mass matrices can then be input into the finite element computer program just as the physical mass, with the exception that unlike the physical mass, the hydrodynamic mass, being a pressure, is effective only in the normal direction of the shell. Hence, the hydrodynamic mass should be associated only with the normal degree of freedom.

In the incompressible fluid approximation where the hydrodynamic mass matrix is independent of frequency, solution of the coupled fluid-shell dynamic problem is straightforward. In general, however, the hydrodynamic mass matrix is a full matrix with frequency dependent matrix elements. Solution of the coupled fluid-shell problem involves iteration between calculation of the mass matrix elements and the finite element computer program. When some of the coupled natural frequencies are near to the classical hard-walled acoustic modal frequencies, the hydrodynamic masses become extremely sensitive to the frequencies and solution to the coupled fluid-shell system can be difficult.

The method reported in Ref. 149 greatly simplifies the above computational procedure by reducing the size of the matrix, while still giving reasonable estimates of the coupled frequencies of the fluid shell system. It consists of calculating the 2×2 “generalized” hydrodynamic mass matrix, $\bar{H}_{mn}^a$, $\bar{H}_{mn}^b$, $\bar{H}_{mn}^{ab}$, and $\bar{H}_{mn}^{ba}$ of the cylindrical shells a and b , and uniformly distributing these hydrodynamic masses over the cylindrical surfaces. For the off diagonal elements, $\bar{H}_{mn}^{ab}$, $\bar{H}_{mn}^{ba}$, it is assumed that coupling exists only for elements of the cylinders that are directly opposite to each other. The resulting mass matrix is tri-diagonal instead of full, and greatly simplifies the computational procedure. The tri-diagonal hydrodynamic mass matrix approach yielded natural frequencies of a coupled fluid-shell system that agree quite well with those obtained from closed form solution.

TEXT

N-1460 FORCED RESPONSE OF COUPLED-SHELL SYSTEM

When the motion of the shells is small, the equation of motion for forced response of a coupled fluid-shell system can be written as:

$$[\mu](\ddot{q}) + [C](\dot{q}) + [K](q) = (f_o) + (f) \quad (126)$$

(126)

where ν is the equivalent hysteretic damping factor, f_o is the incident force acting on the shells, which is present irrespective of the motion of the shells. Examples of f_o are random pressure caused by turbulent boundary layers, or transient pulses caused by shock waves impinging on the shells. f is the reaction pressure induced on the shell as a consequence of its own motion: a result of the interaction (or coupling) between the fluid and the structure. From Eq. (109),

$$(127) \{f\} = (p \cdot \Delta A) = [M_H][\delta_{33}]\{\bar{q}\}$$

so that Eq. (126) becomes,

$$(128) ([\mu] + [M_H][\delta_{33}])\{\bar{q}\} + [C]\{q\} + [K]\{q\} = [f_o(t)]$$

Equation (128) is exactly the same as the equation of motion in-air with the forcing function f_o . The only difference is that added to the physical mass matrix $[\mu]$ is a hydrodynamic mass matrix M_H , which is effective only in the normal direction of the shells. Thus, once the hydrodynamic mass matrix is computed, the dynamic problem can be solved routinely, by finite element structural analysis computer programs or otherwise, as if there were no coupling between the fluid and the structure.

N-1470 HYDRODYNAMIC DAMPING

Just as the fluid mass adds to the effective mass of cylindrical shells, the viscosity of the entrapped fluid adds to the effective damping of the coupled fluid-shell system. This hydrodynamic damping, or added damping, due to coupling of a cylindrical structure and a viscous fluid, was studied by Chen (Refs. 90 and 146), Yeh and Chen (Ref. 157), and Mulcahy (Ref. 158). It was shown that the equivalent hydrodynamic modal damping ratio is dependent on a dimensionless parameter,

$$(129) S = \omega a^2 / \nu,$$

where ν is the kinematic viscosity of the entrapped fluid. The general expression for the hydrodynamic damping ratio, like that for the hydrodynamic mass, is quite complicated. Some insight, however, can be gained by studying the special case of the beam mode ($n = 1$) vibration of an infinitely long cylinder of radius a inside a stationary cylinder of radius b . In

Page 415

this case, the equivalent hydrodynamic modal damping ratio is given by

$$(130) \zeta_1 = - [0.5\pi a^2 / (M_H + \mu a^2)] \text{Im}(Z)$$

where Z is a fairly complicated function of modified Bessel functions and S . Figure N-1470-1, reproduced from Ref. 146, gives theoretical values of $-\text{Im}(Z)$ as a function of the radius ratio b/a , for different values of S , and shows that as $S \rightarrow \infty$, $-\text{Im}(Z)$ becomes infinitesimal even for small ratios of b/a , indicating that hydrodynamic damping is negligible for large values of S . As an example, for the vibration of the core support structure of a typical nuclear reactor inside the reactor vessel, $S \approx 10^9$. Thus, the hydrodynamic damping in this case is negligible. This conclusion, however, may not be true for the vibration of a thin rod inside a fluid-filled jacket of slightly larger diameter.

Although the above example is for the beam mode vibration of an infinitely long cylinder, the same conclusion holds true qualitatively for the shell mode vibration of finite cylindrical shells. This theoretical deduction is also supported by experimental observations. Damping ratios of thermal shields measured during pre-operational tests of pressurized water reactors show little difference from their corresponding values measured in-air. Thus, hydrodynamic damping in large cylindrical structures can be ignored.

N-1500 FLUID TRANSIENT DYNAMICS

In the course of preparation.

N-1600 MISCELLANEOUS IMPULSIVE AND IMPACTIVE LOADS

In the course of preparation.

N-1700 COMBINED RESPONSES

N-1710 DYNAMIC RESPONSE COMBINATION

In the design of nuclear power components it is necessary to consider the combined responses caused by two or more different sources of dynamic loading. There are two situations which arise: one in which the time phase relationship between

the two or more responses is known (deterministic); and a second, where the time phase relationship is said to be random. In the first situation, the response may be determined by the algebraic summation method of N-1720. In the second case where the time phase relationship is random, one of the three methods N-1721, N-1722, or N-1723 may be used depending upon satisfying the qualifying conditions contained in N-1721, N-1722, or N-1723. The owner, either directly or through his designee, may prescribe whether the time phase relationship of individual load responses is to be considered deterministic or random. Consideration may be given to the probability of occurrence of the associated events which cause the combined loading in arriving at detailed procedures for combining randomly phased responses (see discussion in N-1725).

N-1720 ALGEBRAIC SUMMATION

When the time phase relationship between two or more time history responses is known and the dynamic system is linear, the individual collinear responses may be algebraically added to determine the combined maximum and minimum structural response. If the dynamic system is nonlinear, then the combination loading should be input into the dynamic system analysis in order to determine the combination response.

N-1721 Peak Combined Response

In those cases where the dynamic system is linear and where two or more responses are to be combined, the peaks of the individual collinear responses can always be conservatively added to obtain the combined response irrespective of whether the phase relationship of the responses is undefined, deterministic, or random.

N-1722 SRSS (Square Root of Sum of Squares) Method

N-1722.1 For Responses With Nearly Equal Dominant Frequencies.

In those cases where the dynamic system is linear and where (a) the time phasing of the peak individual collinear responses is random and (b) all of the individual responses have nearly an equal dominant¹ frequency with arbitrary amplitude, the SRSS method may be used to determine the combined design response (Refs. 68, 69, and 70).

¹ An individual time history response may be considered to have dominant frequency if one-half or more of its total response can be identified with a single frequency.

N-1722.2 For Uncorrelated Dynamic Responses.

The intent of this method for combination of transient

Page 416

dynamic responses is to achieve a conditional nonexceedance probability of at least 50% for the peak combined response of the system, component, or element considered. That is, there is a 50% probability that the magnitude of the summed responses will not exceed the SRSS value, given that the combined events have occurred. This goal is achieved by compliance with the following criteria provided that the amplitude of loads or accelerations for each input are conservatively represented (approximately at the level of the 84th percentile or the mean plus one standard deviation of the input amplitude).

FIG. N-1470-1 IMAGINARY PART OF Z AS A FUNCTION OF b/a FOR SELECTED VALUE OF S (REF. 146)

FIG. N-1470-1 IMAGINARY PART OF Z AS A FUNCTION OF b/a FOR SELECTED VALUE OF S (REF. 146)

R_{m1} = absolute maximum response
 $R_{+75} = 0.75 |R_{m1}|$
 $R_{-75} = -0.75 |R_{m1}|$
 T_{+75} = summation of time intervals that response exceeds R_{+75}
 T_{-75} = summation of time intervals that response exceeds R_{-75}
 T_{75} = larger of T_{+75} or T_{-75}
 $\Delta T = T_1$, since $T_1 > T_2$

FIG. N-1722.2-1 DEFINITION OF NOTATION

FIG. N-1722.2-1 DEFINITION OF NOTATION

Criterion. Dynamic or transient responses of linear structures, components, and equipment arising from combinations of dynamic loading or motions may be combined by SRSS provided that each of the dynamic inputs or responses has a

limited number of peaks of force or acceleration and *approximately a zero mean*, and that the individual component inputs can be considered to be *relatively uncorrelated* (Refs. 75 to 78). Specific criteria for these three requirements are given below.

The requirement of a *limited number of peaks* is satisfied if any one of the following three criteria is met.

(a) For each response time history in the combination:

$$\frac{T_{75}}{\Delta T} \leq 0.02$$

and

$$\frac{T_{50}}{\Delta T} \leq 0.08$$

where T_{75} represents the summation of time intervals for all peaks over which the response exceeds 75% of either the maximum or minimum response (whichever is greater), T_{50} represents the time over which the response exceeds 50% of either the maximum or minimum response (whichever is greater), and ΔT represents the total time interval over which the maximum responses are expected to occur. For the case of random relative start times, ΔT represents the time interval during which the strong responses may overlap (generally taken as the time interval from the zero crossing time just preceding the first peak that exceeds 50% of the absolute maximum response to the zero crossing time just following the last peak that exceeds 50% of the absolute maximum response, of the longer time history). The strong motion of a seismic time history is discussed in N-1212.2(f). In determining the time T_{75} and T_{50} only the durations of peaks with the same sign (positive or negative) are additive. These definitions are illustrated in Fig. N-1722.2-1.

(b) For each input-time history in the combination:

$$\frac{T_{75}}{\Delta T} \leq 0.01$$

and

$$\frac{T_{50}}{\Delta T} \leq 0.04$$

where the definitions are the same as above, except for the substitution of input for response.

(c) If criteria (a) or (b) above are not met by each of the responses or inputs, respectively, in the combination, this requirement is still satisfied if the effective time ratios $(T_{75}/\Delta T)_e$ and $(T_{50}/\Delta T)_e$ for the response combination meet the requirements of (a) above. The effective time ratios for the response combination are given by:

$$\left(\frac{T_{75}}{\Delta T} \right)_e = \sqrt{\frac{\sum_{i=1}^N (R_m T_{75} / \Delta T)_i^2}{\sum_{i=1}^N (R_m)_i^2}}$$

where i represents each individual response in the combination and $(R_m)_i$ represents the maximum amplitude of that response component. The effective time ratio $(T_{50}/\Delta T)_e$ is obtained by substituting 50 for 75 in the above equation.

The requirement of *approximately a zero mean* is satisfied if, for the duration of strong input (or response), the ratio of the mean to maximum input (or response) is less than 0.20. The mean value is:

$$\mu = \frac{1}{N} \sum_{j=1}^n R_j$$

where μ is the mean value, R_j is the response at time increment j , and N is the total number of equally spaced time increments.

If this requirement is not met, responses can be divided into two parts (nonzero mean part and peak response relative to mean response) provided the response function is not skewed from the axis of the mean μ . The nonzero mean part of response can be combined algebraically (accounting for the sign of the mean response) and the peak responses relative to the mean responses can be combined SRSS if these relative responses meet the provisions of this section.

Page 419

The requirement of *relatively uncorrelated* inputs is met if either of the following is satisfied: (1) the individual dynamic inputs or responses are from events such that their relative start times are uncertain; (2) if the relative start times are known, then the coefficient of correlation must be less than 0.3.

N-1723 SRSSE (Equivalent SRSS) Method

(a) In those cases where individual linear system time history responses have randomly defined time phase relationships and condition (b) of N-1722 is not satisfied, the SRSSE method may be used to determine the combined design response. As an illustration, N-1723.1 and N-1723.2 describe a detailed numeric procedure for determining the combinations for the case where two individual time history responses have a uniform random time phase relationship.

(b) For the case when three or more linear time history responses are to be combined, the procedures of N-1724 may be used to determine the combined SRSSE design responses (Ref. 68).

N-1723.1 SRSSE Method for Two Time History Responses.

A method may be constructed to obtain the SRSSE response combinations as given in (a), (b), and (c) below.

(a) Determine one time history as a reference function. Bring the origin of the second function coincident with the origin of the reference function. Care should be taken to determine the reference function so that the time shift of the second function is consistent with the actual sequence of events expected. The origin of the second function could occur at, before, or after the origin of the reference function. The case where the origins are coincident will be discussed in (b) and (c) below. The procedure for the other two cases are similar.

(b) Shift the second function in small time steps relative to the reference function until the origin of the second function goes to the end of the reference function (see Fig. N-1723.1-1). For each time phase difference τ , a scan is made from the time zero to $t_{gr} + T_2$ if $(t_{gr} + T_2) \leq T_1$, or from the time zero to $(t_{gr} + T_2) < T_1$ to determine the largest amplitude (peak) of the sum of the two functions. T_1 and T_2 are the time duration of the reference function and second function, respectively. The algebraic maximum and minimum of these peaks, Maximum Combined Amplitude (FF), are plotted as functions of the time phase difference τ . The resulting function is called the Amplitude Phase Function (APF) which is shown in Fig. N-1723.1-3

(c) The functional relationship between the APF and the Probability Density Function (PDF) for the time shift (Fig. N-1723.1-2) is then used to compute the cumulative Distribution Functions (CDF) of the maximum and minimum combined amplitudes as detailed in N-1723.1.1 (Fig. N-1723.1-4). The choice of the appropriate PDF for τ should be developed on a case-by-case basis. The uniform PDF is frequently a reasonable assumption when there is a weakly known cause and effect between the initiation of the causative events.

N-1723.1.1 Cumulative Distribution Function (CDF).

Both the maximum and minimum Cumulative Distribution Functions need to be constructed.

(a) From Fig. N-1723.1-3, which illustrates the maximum APF function, it can be seen that any possible combined amplitude FF falls between two extreme limits $FF_{\max}$ and $FF_{\min}$. It is clear that the probability that the value of FF is less than $FF_{\max}$ is one, and the probability that the value of FF is less than $FF_{\min}$ is zero. Hence, in Fig. N-1723.1-4, we can immediately plot these two extreme points.

(b) The intermediate points on the CDF are found by integration of the distribution of the time shift τ between appropriate limits. Hence, at this point, the choice of the distribution for τ enters the calculations.

(c) Calculation of the intermediate points on the CDF requires the consideration of the functional relationship between the maximum combined amplitude FF and the time phase shift τ . For a given value of FF on Fig. N-1723.1-3 (in this case FF_1) there is an interval on the τ axis (τ_2, τ_3) in Fig. 1723.1-3. This same τ interval (τ_2, τ_3) can also be observed on the Probability Density Function for τ in Fig. N-1723.1-2. The shaded area of Fig. N-1723.1-2 represents the probability that τ falls in the interval (τ_2, τ_3). The event of τ falling in the interval (τ_2, τ_3) corresponds exactly to the event that FF is less than or equal to FF_1 . Therefore, the ordinate P of Fig. N-1723.1-4 corresponding to FF_1 can be computed as

$$P_1 = \int_{\tau_2}^{\tau_3} \text{PDF}(\tau) d\tau \quad (131)$$

(131)

and for the case where

$$(132) \text{PDF}(\tau) = 1/T_1$$

then

$$(133) P_1 = (\tau_3 - \tau_2)/\tau_1$$

(d) The same procedure is followed for other levels of FF. Note that care must be exercised when integrating

Page 420

multiple valued functions to avoid a loss of information. If the level of FF selected contains more than one interval of τ , all intervals must be integrated to obtain the associated probability. For example, in the case of FF, the integration limits in Eq. (131) would be from τ_1 to τ_4 and from τ_5 to τ_6 . The result of the integration is designated P_2 and plotted in Fig. N-1723.1-4.

FIG. N-1723.1-1

FIG. N-1723.1-1

FIG. N-1723.1-2

FIG. N-1723.1-2

FIG. N-1723.1-3

FIG. N-1723.1-3

FIG. N-1723.1-4

FIG. N-1723.1-4

(e) Selecting different levels of FF and repeating the above procedure, the CDF function as shown in Fig. N-1723.1-4 can be constructed.

(f) This entire procedure is then repeated for the minimum APF function to find its corresponding CDF.

N-1723.1.2 Cumulative Distribution Function for the Absolute Maximum.

An alternative and more conservative procedure than that given in N-1723.1.1 may also be used to generate the CDF of combined responses. In this alternative procedure, instead of summing the positive and negative peaks of the response separately as in N-1723.1.1, the absolute value of the peak combined response is identified for each value of τ when generating the APF. In this alternative procedure, a single APF is generated which corresponds to a combination of both positive or negative combined responses, whichever is greater in absolute magnitude for each value of τ . The procedure to construct the absolute maximum CDF is the same as stated in N-1723.1.1, except that only one CDF is generated for each response combination instead of two.

N-1723.2 SRSSE Values.

From the maximum and minimum CDF determined in N-1723.1.1, select the values for SRSSE maximum and SRSSE minimum combinations corresponding to the 50% probability levels. It should be noted that these 50% levels are conditional probability levels given that the causative events have occurred. In order to determine total probability levels associated with the SRSSE values, it is necessary to multiply by the corresponding simultaneous combined event occurrence as illustrated in Ref. 70.

N-1724 SRSSE Method for Three or More Functions

A Monte Carlo simulation procedure (Refs. 69 and 70) will generally be required to generate the CDF if there are more than two time history response functions to be combined. The SRSSE maximum, minimum, or absolute maximum values are at the same 50% probability levels used in N-1723.2.

N-1725 Alternative CDF Values

The SRSSE values of N-1723.2 and N-1724 are at a conditional nonexceedance probability level of 50%. That is, there is a 50% probability that the magnitude of the summed responses will not exceed the SRSSE values, given that the combined events have occurred. When the peak combined response values of N-1721 are used, the 100% nonexceedance values result. Since the use of either of these levels (50%, 100%) must be specified through consideration of systems requirements and service levels, alternative nonexceedance probability levels between 50% and 100% may also be used.

SEC III D1 NMA APP O

APPENDIX O RULES FOR DESIGN OF SAFETY VALVE INSTALLATIONS

Page 429

ARTICLE O-1000 RULES FOR DESIGN OF SAFETY VALVE INSTALLATIONS

O-1100 SCOPE AND DEFINITION

O-1110 SCOPE

(a) The scope of Appendix O is confined to the design of the safety valve installations as defined in O-1120. The loads acting at the safety valve station will affect the bending moments and stresses in the complete piping system, out to its anchors and/or extremities, and it is the designer's responsibility to consider these loads. This Appendix, however, deals primarily with the safety valve installation and not the complete piping system.

(b) The design of the safety valve installation requires that careful attention be paid to all loads acting on the system, the forces and bending moments in the piping and piping components resulting from the loads, the loading and stress criteria, and general design practices. All components in the safety valve installation must be given consideration, including the complete piping system, the connection to the main header, the safety valve, valve and pipe flanges, the downstream

discharge or vent piping, and the system supports. The scope of this Appendix is intended to cover all loads on all components.

(c) This Appendix has application to either safety, relief, or safety relief valve installations. For convenience, however, the overpressure protection device is generally referred to as a safety valve. The loads associated with relief or safety relief valve operation may differ significantly from those of safety valve operation, but otherwise the rules contained herein are equally applicable to each type of valve installation.

(d) Pressure relief safety valve stations require detailed analysis. In performing its design function the station is subject to dynamic loading from the structural response to both thermal and hydraulic forces and, in some instances, significant impact loading from the valve mechanism. The resultant loading is a mechanical load.

(e) This Appendix provides guidance for design and analysis of the piping components of a safety valve station. The guidance is presented by discussing four areas of consideration:

- (1) load computation - open discharge system;
- (2) stress evaluation - open discharge system;
- (3) closed discharge system;
- (4) general design considerations.

O-1120 DEFINITIONS

(a) *Safety Valve*. An automatic pressure relieving device actuated by the static pressure upstream of the valve and characterized by full opening pop action. It is used for gas or vapor service.

(b) *Relief Valve*. An automatic pressure relieving device actuated by the static pressure upstream of the valve which opens further with the increase in pressure over the opening pressure. It is used primarily for liquid service.

(c) *Safety Relief Valve*. An automatic pressure actuated relieving device suitable for use either as a safety valve or relief valve, depending on application.

(d) *Power-Actuated Pressure Relieving Valve*. A relieving device whose movements to open or close are fully controlled by a source of power (electricity, air, steam, or hydraulic). The valve may discharge to atmosphere or to a container at lower pressure. The conditions, and such effects, shall be taken into account. If the power-actuated pressure relieving valves are also positioned in response to other control signals, the control impulse to prevent overpressure shall be responsive only to pressure and shall override any other control function.

(e) *Open Discharge Installation*. An installation where the fluid is discharged directly to atmosphere or to a vent pipe that is uncoupled from the safety valve. Figure O-1120(e)-1 shows a typical open discharge

Page 432

installation with an elbow installed at the valve discharge to control direction of flow. Figure O-1120(e)-2 shows a typical open discharge system discharging into a vent pipe. The values for l and m in Fig. O-1120(e)-2 are upper limits for which the rules for open discharge systems may be used.

**FIG. 0-1120(e)-1 APPLICATION POINT OF VENTING
FORCE F**

FIG. 0-1120(e)-1 APPLICATION POINT OF VENTING FORCE F

$$l \leq 4.0 \times \text{discharge pipe diameter}$$

$$m \leq 6.0 \times \text{discharge pipe diameter}$$

FIG. O-1120(e)-2 LIMITING SAFETY VALVE ARRANGEMENTS AND DIMENSIONS

FIG. O-1120(e)-2 LIMITING SAFETY VALVE ARRANGEMENTS AND DIMENSIONS

(f) *Closed Discharge Installation.* An installation where the effluent is carried to a distant spot by a discharge pipe which is connected directly to the safety valve.

(g) *Safety Valve Installation.* The safety valve installation is defined as that portion of the system shown on Figs. O-1120(e)-1 and O-1120(e)-2. It includes the run pipe, the branch connection, the inlet pipe, the valve, the discharge piping,

and the vent pipe. Also included are the components used to support the system for all static and dynamic loads.

O-1200 METHOD OF AND PROCEDURE FOR LOAD COMPUTATION

O-1210 BASIC CONSIDERATIONS

(a) The load computation includes two thermodynamic computations: evaluation of momentum effects and evaluation of pressure effects. The response computation of the piping system includes consideration of transient, dynamic loading effects of the sudden opening and closing valve action. The loads computation is combined with other specified loads and translated to a stress computation which is then compared to the Code allowable stress for acceptability.

(b) The basic principles of analysis of a pressure relief valve station are generally applicable to both open and closed discharge systems. The application of these basic principles may be quite different.

O-1220 OPEN SYSTEM - DISCHARGE THRUST

(a) The limiting dimensions for safety valve arrangements are shown by Fig. O-1120(e)-2. The determination of the reaction force F value(s) is the responsibility of the piping system designer.

(b) The steady-state load due to steam reaction force from the opening and subsequent venting of the safety valve shall include consideration of both momentum and pressure effects and may be computed by the formula:

$$F = (W/g) V_e + (P_e)A$$

where

F	= reaction force, lbf
W	= mass flow rate (relieving capacity stamped on the valve × 1.11 - adjust for units to be compatible, if necessary), lbm/sec
g	= gravitational constant, 32.2 lbm-ft/lbf-sec ²
V_e	= exit velocity at point e , ft/sec
P_e	= static gage pressure at point e , lbf/in. ²
A	= exit flow area at point e , in. ²

The reaction force F is a design mechanical load that requires structural equilibrium for system stability and is applied as shown in Fig. O-1120(e)-1.

(c) To ensure consideration of the effects of the suddenly applied load F , a dynamic load factor DLF, based on the relief/safety valve opening time and system dynamic characteristics, shall be applied to the forces and moments due to the reaction force F .

(d) Instead of a simplified dynamic analysis with the application of the DLF a dynamic hydraulic/structural system analysis may be performed.

O-1230 OTHER MECHANICAL LOADS

Other mechanical loads to be considered should include, as a minimum:

- (a) interaction loads on the run pipe when more than one valve releases; and
- (b) the transient impacting of the valve mechanism opening and closing, if applicable.

O-1300 STRESS EVALUATION OPEN SYSTEM

Evaluation of stresses due to the design mechanical loads may be made by using the rules for Class 1 piping, O-1310 and for

Class 2 or Class 3 piping, O-1320.

O-1310 CLASS 1 PIPING

(a) Whenever any of the equations of NB-3650 are used in the analysis of Class 1 piping systems, the value of M_i shall include the reaction force moment. The contribution from the reaction force F to the branch moment M_b , as defined in Note (5) of Table NB-3682.2-1, shall be no less than the product $F \times \text{nominal discharge pipe size} \times \text{DLF}$.

(b) Note that the use of the equations of NB-3650 for branch connections requires a nozzle spacing as defined by NB-3686.1(c).

(c) When Eq. (9) of NB-3650 is used in the analysis, the value of M_i shall be defined as:

M_i	= resultant moment due to a combination of primary loads. Loads to be considered include: weight; earthquake, considering only one-half the range of the earthquake and excluding the effects of anchor displacement due to earthquake; thrusts from relief and safety valve loads from pressure and flow transients; and other sustained mechanical loads.
-------	---

(d) The combination of loads shall be specified in the Design Specification. In the combination of loads, all directional moment components in the same direction shall be combined before determining the resultant moment; i.e., resultant moments of loads shall not be combined.

(e) When Eq. (10) is used in the analysis, the value of M_i shall be defined as:

M_i	= resultant range of moment due to a combination of primary plus secondary loads. Loads to be considered include: thermal expansion; anchor movement from any cause; earthquake effects; thrusts from relief and safety valve loads from pressure and flow transients; and other mechanical loads.
-------	--

(f) The combination of loads shall be specified in the Design Specification. The earthquake loading shall be considered in conjunction with the operating conditions. Weight effects need not be considered in the range loading because they are noncyclic in character. In the combination of loads, all directional moment components in the same direction shall be combined before determining the resultant moment; i.e., resultant moments of loads shall not be combined. If a combination includes earthquake effects, M_i shall be the greater of the resultant range of moment due to the combination of all loads considering one-half the range of the earthquake or the resultant range of moment due to the full range of the earthquake.

O-1320 CLASS 2 OR CLASS 3 PIPING

(a) For Class 2 or Class 3 piping, Eq. (9) of NC-3652 or ND-3652 is to be used with M_b to include the reaction force moment. The contribution from the reaction force F to the branch moment, as defined in NC-3652.4 or ND-3652.4, shall be no less than the product, $F \times \text{nominal discharge pipe size} \times \text{DLF}$.

(b) Note that the use of Eq. (9) of NC-3652 or ND-3652 for branch connections requires a nozzle spacing, as defined by NC-3643.3(c)(6) or ND-3643.3(c)(6).

O-1400 CLOSED DISCHARGE SYSTEMS - OPEN DISCHARGE SYSTEMS WITH LONG DISCHARGE PIPES - SYSTEMS WITH SLUG FLOW

(a) For closed discharge systems, open discharge systems with long discharge pipes, and systems with slug flow, the state of the art does not lend itself to

Page 434

a well defined method of load computation. For these systems the dynamic interaction forces of the total system including the attached discharge piping must be considered.

(b) When a safety valve discharge is connected to a relatively long run of pipe and is suddenly opened, there is a period of transient flow until the steady-state discharge condition is reached. During this transient period, the pressure and flow will not be uniform. When the safety valve is initially opened, the discharge pipe may be filled with air. If the safety valve is on a steam system, the steam discharge from the valve must purge the air from the pipe before steady state steam flow is established and, as the pressure builds up at the valve outlet flange and waves start to travel down the discharge pipe, the pressure wave initially emanating from the valve will steepen as it propagates, and it may steepen into a shock wave before it reaches the exit.

(c) Relief valves discharging into an enclosed piping system create momentary unbalanced forces which act on the piping system during the first few milliseconds following relief valve lift. The pressure waves traveling through the piping system following the rapid opening of the safety valve will cause bending moments in the safety valve discharge piping and throughout the remainder of the piping system. In such a case, the designer must compute the magnitude of the loads and perform appropriate evaluation of their effects.

(d) Particular attention should be given to the large forcing functions acting on the pipe if it contains water seals, two phase flow, or if there is a water column in the discharge piping.

(e) The reaction force effects are dynamic in nature. A time history dynamic solution, incorporating a multi-degree-of-freedom model solved for the transient hydraulic forces is considered to be a preferred method of analysis.

O-1500 DESIGN CONSIDERATIONS

Reference should be made to NB/NC/ND-7000.

It is recommended that the following be included as part of the total design consideration.

(a) Where not required by the Code, it is recommended that the header penetrations for relief valves be in accordance with the nozzle spacing recommendation of NB-3686.1(c).

(b) No more than one penetration should be made around the circumference of the run pipe (i.e., no two penetrations in the same transverse plane), the spacing to be in accordance with (a) above.

(c) The stress analysis of the pipe could require additional thickness for membrane protection above that required by the thickness equation for pressure load only.

(d) Detail design should preclude sharp notches that may be generated by the use of saddles, gussets, ribs, etc.

(e) Contoured outlets are often advantageous.

(f) The direction of discharge of several pressure relief valves on the same run pipe should be such as to tend to balance one another for all modes of operation specified in the piping design specification.

(g) Supports may require a detailed analysis to determine their role in restraint as well as support. Considerations should be given to the possibility that, under load, snubbing devices may permit significant deflections.

(h) The reaction force moment arm on the outlet piping should be minimized in accordance with the valve manufacturer's recommendation.

(i) The relief valve outlet piping stack clearance should be checked for interference from thermal expansion, earthquake displacements, etc. The vent stack and valve discharge piping system should be arranged such that pull out of the valve discharge pipe does not occur.

(j) Thermal expansion effects are to be considered as they presently are defined in the Code.

(k) The force due to venting should be included in the evaluation of the stack forces. The effects of back pressure in the discharge stack can be significant.

(l) The station should be arranged such that the discharge piping is void of collected water. The discharge piping from each valve or device should be at least of the same size as the valve outlet.

(m) Drains shall be provided so that condensed leakage, rain, or other water sources will not collect on the discharge side of

the valve and adversely affect the reaction force. Safety valves are generally provided with drain plugs that can be used for a drain connection. Discharge piping shall be sloped and provided with adequate drains if low points are unavoidable in the layout.

(n) Where water seals are used ahead of the safety valve, the total water volume in the seals should be minimized. To minimize forces due to slug flow or water seal excursion, the number of changes of direction and the lengths of straight runs of piping should be limited.

(o) Often safety valves are full lift, pop-type valves and are essentially full flow devices with no capability for flow modulation. In actual pressure transients, the steam flow required to prevent overpressure is a varying quantity, from zero to the full rated capacity of the

Page 435

safety valves. As a result, the valves may be required to open and close a number of times during the transient. Since each opening and closing produces a reaction force, consideration should be given to the effects of multiple valve operations on the piping system, including supports.

APPENDIX P CONTENTS OF CERTIFIED MATERIAL TEST REPORTS

Page 437

ARTICLE P-1000 CERTIFIED MATERIAL TEST REPORTS

P-1100 INTRODUCTION

The requirements for a Certified Material Test Report (CMTR) are stated in NCA-3860. However, the material requirements vary with the class of construction, the product form of material, the requirements of the material specification, and the manufacturer's procedures. Since changes in any of these requirements may be made by Addenda or new editions of the Code, it is important for the purchaser and the supplier to know the requirements of the applicable edition and Addenda, so that the reported results can be compared with the requirements to determine whether or not the material is in compliance with the Code.

P-1200 GENERAL REQUIRED INFORMATION

The items of information given in (a) through (i) below are required in the CMTRs for metallic material (as defined by NCA-1220 and NB/NC/ND/NE/NF/NG-2100) used in Section III, Division 1, construction.

- (a) Name of certifying organization [P-1200(j)].
- (b) Number and expiration date of the organization's Certificate of Authorization or Quality System Certificate (Materials). Alternatively, if the organization was qualified by a party other than the Society, the revision and date of the written program under which the material is being certified.
- (c) Purchaser's order or contract number.
- (d) Description of the material, including specification number, grade, class, type, and nominal size, as applicable. For pipe made to specifications which include both seamless and welded pipe, the report shall designate which type it is.
- (e) Description of material identification marking.
- (f) Actual results of chemical analyses, tests, and examinations required by the Material Specification and this Section.
- (g) Reports of weld repairs performed, if any, as required by NB/NC/ND/NE/NF/NG-2500, including radiographic films, when radiography is required.

(h) Charpy V-notch and drop-weight test results required by NB/NC/ND/NE/NF/NG-2320, when this testing is required by NB/NC/ND/NE/NF/NG-2311. When Charpy V-notch impact tests are required, the report shall include the test temperature; the absorbed energy when required; the lateral expansion; and the location and orientation of the specimens used. When drop-weight tests are required, the report shall include the test temperature; the type, location, and orientation of the specimens used; and the results of the tests (break or no break).

(i) Nondestructive examinations performed and accepted as required by NB/NC/ND/NE/NF/NG-2500.

P-1300 INFORMATION REQUIRED UNDER SPECIFIC CIRCUMSTANCES

The information given in (a) through (f) below is required under specific circumstances.

(a) Heat treatment data, as follows:

(1) temperatures (or temperature ranges) and times at temperature used when the material specification requires specific temperatures and times;

(2) heat treatment conditions when no specific temperatures (or temperature ranges) or times are required by the material specification;

(3) the minimum solution annealing temperature used for austenitic stainless steels and high nickel alloys;

(4) recorded temperature ranges and actual times at temperature, and heating and cooling rates, for postweld heat treatment of materials that are repaired by welding, when postweld heat treatment is required by NB/NC/ND/NE/NF/NG-2500;

Page 440

(5) recorded temperatures and actual times at temperature for test coupons when required by NB/NC/ND/NE/NF/NG-2500, when those paragraphs are applicable.

(b) Hydrostatic test pressure, when a hydrostatic test is required by the material specification, or notation that the hydrostatic test has not been performed, if it is deferred.

(c) Ferrite Number for all A-No. 8 welding material except type 16-8-2, as required by NB/NC/ND/NE/NF/NG-2500.

(d) The grain size, reported in accordance with ASTM E 112, when a fine grain size is specified for metallic materials.

(e) For welding materials, in addition to applicable paragraphs above, the process, the preheat and interpass temperature, the type of chemical analysis (filler metal/undiluted deposit), the shielding gas composition, and the Ferrite Number shall be reported as required by NB/NC/ND/NE/NF/NG-2500 and as applicable.

(f) A list of chemical analyses, tests, examinations, and heat treatments required by the Material Specification that were not performed.

P-1400 EXECUTION

(a) All requirements of the material specification and this Section need not be performed by the same organization. In that case the certifying organization shall ensure that each organization, providing material or services, is identified on the CMTR along with the activities for which it is responsible. Alternatively, the CMTR's furnished by the other organizations may be referenced on and attached to the CMTR of the organization which supplies the material.

(b) The CMTR shall include a dated statement affirming that the contents of the report are correct and accurate.

(c) Signing or notarization of the CMTR is not required.

SEC III D1 NMA APP Q

APPENDIX Q DESIGN RULES FOR CLAMP CONNECTIONS

Page 441

ARTICLE Q-1000 DESIGN RULES FOR CLAMP CONNECTIONS

Q-1100 INTRODUCTION

Q-1110 SCOPE

(a) The rules in Appendix Q apply specifically to the design of clamp connections for pressure vessels and vessel parts and may be used in conjunction with the applicable requirements in Subsections NC, ND, and NE. These rules are not to be used for the determination of the thickness of supported or unsupported tube sheets integral with a hub nor for the thickness of covers. These rules provide only for hydrostatic end loads and gasket seating and do not consider external loads or thermal effects.

(b) The design of a clamp connection involves the selection of the gasket, bolting, hub, and clamp geometry (see Fig. Q-1130-1). Bolting shall be selected to satisfy the requirements of Q-1140. Connection dimensions shall be such that the stresses in the clamp and hub, calculated in accordance with this Appendix, do not exceed the allowable stresses specified in Q-1180. All calculations shall be made on dimensions in the corroded condition. Calculations for both assembly and operating conditions are required.

(c) It is recommended that either a pressure energized or a low seating load gasket, or both, be used to compensate for possible nonuniformity in the gasket seating force distribution. Hub faces shall be designed so as to have metal-to-metal contact outside the gasket seal diameter. This may be provided by recessing the hub faces or by use of a metal spacer (see Fig. Q-1130-1). The contact area shall be of sufficient cross-sectional area to prevent yielding of either the hub face or spacer under both operating and assembly axial loads.

(d) It is recognized that there are clamp designs which utilize no wedging action during assembly since clamping surfaces are parallel to the hub faces. These designs should satisfy the bolting and corresponding clamp and hub requirements of a clamp connection design with a total included clamping angle of 10 deg. This will provide some safety against loads imposed by angular deflections of the connection faces during operation and also provide some compensation against mechanical and thermal ratcheting.

(e) The rules of this Appendix should not be construed to prohibit the use of other types of clamp connections provided that they are designed in accordance with good engineering practice and the method of design is acceptable to the Inspector. These rules shall apply only to new construction.

(f) Clamps designed to the rules of this Section shall be provided with a bolt retainer. The retainer shall be designed to hold the clamps together independently in case of failure of the primary bolting. An appropriate external yoke or multiple bolting is considered satisfactory for this requirement. Clamp-hub friction shall not be considered as a retainer method.

Q-1120 MATERIALS

(a) Materials used in the construction of clamp connections shall comply with the requirements given in NC, ND, or NE-2000, as applicable.

(b) Hubs and clamps shall not be machined from plate.

Q-1130 NOTATION

The symbols defined below are used in the formulas for the design of clamp-type connections (see also Figs. Q-1130-1 and Q-1130-2).

A	= outside diameter of hub, in.
A_b	= total cross-sectional area of bolts per clamp lug using the root diameter of the thread or least diameter of unthreaded portion, whichever is less, sq in. Cross-sectional area of bolt retainer shall not be included in calculation of this area.

A_c

= total effective clamp cross-sectional area, sq in.

$$= A_1 + A_2 + A_3$$

Page 444

Page 445

FIG. Q-1130-1 TYPICAL HUB AND CLAMP

A_1	= partial clamp area, sq in. = $(C_w - 2C_t)(C_t)$
A_2	= partial clamp area, sq in. = $1.571C_t^2$
A_3	= partial clamp area, sq in. = $(C_w - C_g)l_c$
A_{m1}	= total cross-sectional area of bolts per clamp lug at root of thread or section of least diameter under stress, required for the operating conditions, sq in. = $W_{m1}/2S_b$
A_{m2}	= total cross-sectional area of bolts per clamp lug at root of thread or section of least diameter under stress, required for gasket seating, sq in. = $W_{m2}/2S_a$
A_{m3}	= total cross-sectional area of bolts per clamp lug at root of thread or section of least diameter under stress, required for assembly conditions, sq in. = $W_{m3}/2S_a$
A_m	= total required cross-sectional area of bolts per clamp lug taken as the greater of A_{m1} , A_{m2} , or A_{m3} , sq in.
b	= effective gasket or joint-contact surface seating width, in. (see Table XI-3221.1-2)
b_o	= basic gasket or joint-contact surface seating width, in. (see Table XI-3221.1-2)
B	= inside diameter of hub, in.
B_c	= radial distance from connection center line to effective center of bolts, in.
C	= diameter of effective clamp-hub reaction load, in. = $(A + C_i)/2$
C_i	= inside diameter of clamp, in.
C_g	= effective clamp gap taken at clamp-hub contact center (C), in.

C_t	= effective clamp thickness, in.
C_w	= effective clamp width, in.
e_b	= radial distance from effective center of the bolts to the centroid of the clamp body, in.
	$= B_c - (C_t/2) - l_c - X$
f	= hub stress correction factor from Fig. XI-3240-6. (This is the ratio of the stress in the small end of the hub to the stress in the large end.) (For values below limit of the Figure, use $f=1.0$.)
g_o	= thickness of hub neck at small end, in.
g_1	= thickness of hub neck at intersection with hub shoulder, in.
g_2	= height of hub shoulder, in. (g_2 shall not be larger than T)
$\bar{g}$	= radial distance from the hub inside diameter to the hub shoulder ring centroid, in.
	=

$$\frac{Tg_1^2 + h_2g_2(2g_1 + g_2)}{2(Tg_1 + h_2g_2)}$$

G	= diameter at location of gasket load reaction. Except as noted in Fig. Q-1130-1, G is defined as follows (see Table XI-3221.1-2): (a) when $b_o \leq \frac{1}{4}$ in., G = mean diameter of gasket or joint contact face, in. (b) when $b_o > \frac{1}{4}$ in., G = outside diameter of gasket contact face less $2b$, in.
h	= hub taper length, in.
h_D	= radial distance from effective clamp-hub reaction load to the circle on which H_D acts, in. $= [C - (B + g_1)]/2$
h_G	= radial distance from effective clamp-hub reaction load to the circle on which H_G acts, in. (for full face contact geometries $h_G = 0$)
h_n	= hub neck length, in. (minimum length of h_n is $0.5g_1$ or $\frac{1}{4}$ in., whichever is larger)
h_o	= $\sqrt{Bg_o}$ in.

h_T	= radial distance from effective clamp-hub reaction load to the circle on which H_T acts, in. = $[C - (B + G)/2]/2$
h_2	= average thickness of hub shoulder, in. = $T - (g_2 \tan \phi)/2$
$\bar{h}$	= axial distance from the hub face to the hub shoulder ring centroid, in.

$$\frac{T^2 g_1 + h_2^2 g_2}{2 (T g_1 + h_2 g_2)}$$

H	= total hydrostatic end force, lb = $0.785 G^2 P$
H_D	= hydrostatic end force on bore area, lb = $0.785 B^2 P$
H_G	= difference between total effective axial clamping preload and the sum of total hydrostatic end force and total joint contact surface compression, lb = $[1.571 W / \tan(\phi + \mu)] - (H + H_p)$
H_m	= total axial gasket seating requirements for makeup, lb (3.14 bGy or the axial seating load for self-energizing gaskets, if significant)
H_p	= total joint-contact surface compression load, lb = $2b \times 3.14 GmP$ (for self-energized gaskets, use $H_p = 0$ or actual retaining load if significant)
H	

T	hydrostatic end force on bore area, lb
	$= H - H_D$
I_c	= effective moment of inertia of clamp relative to axis of entire section, in. ⁴
	$=$
	$\left(\frac{A_1}{3} + \frac{A_2}{4} \right) C_t^2 + \frac{A_3 l_c^2}{3} - A_c X^2$
I_h	= effective moment of inertia of hub shoulder ring relative to its neutral axis, in. ⁴
	$=$
	$(T^2 g_1 + h_2^2 g_2) \frac{\bar{h}}{6} + \frac{Th_2 g_1 g_2 (T - h_2)^2}{3(Tg_1 + h_2 g_2)}$
L_a	= distance from W to the point where the clamp lug joins the clamp body, in.
L_h	= clamp lug height, in.
L_w	= clamp lug width, in.
l_c	= effective clamp lip length, in.
l_m	= effective clamp lip moment arm, in.
	$= l_c - (C - C_i)/2$
m	= gasket factor from Table XI-3221.1-1
M_D	= component of moment due to H_D , in.-lb
	$= H_D h_D$
M_F	= offset moment, in.-lb
	$= H_D (g_1 - g_o)/2$

M_G

= component of moment due to H_G in.-lb

$$= H_G h_G$$

M_H

= reaction moment at hub neck, in.-lb

=

$$M_O / \left\{ 1 + \frac{1.818}{\sqrt{B g_1}} \left[T - \bar{h} + \frac{3.305 I_h}{g_1^2 (B/2 + \bar{g})} \right] \right\}$$

M_O

= total rotational moment on hub, in.-lb (see Q-1150)

M_P

= pressure moment, in.-lb

$$= 3.14 \times PBT(T/2 - \bar{h})$$

M_R

= radial clamp equilibrating moment, in.-lb

$$= 1.571 W \{ \bar{h} - T + [(C - N) \tan \phi] / 2 \}$$

M_T

= component of moment due to H_T in.-lb

$$= H_T h_T$$

N

= outside diameter of hub neck, in.

P

= Design Pressure, psi

Q

= reaction shear force at hub neck, lb

=

$$1.818 \frac{M_H}{\sqrt{B g_1}}$$

r	= clamp body radius, in. (shall be less than or equal to C_l)
S_a	= allowable bolt stress at atmospheric temperature, psi (see Section II, Part D, Subpart 1, Table 3)
S_b	= allowable bolt stress at Design Temperature, psi (see Section II, Part D, Subpart 1, Table 3)
S_{OH}	= allowable design stress for hub material at (service condition) Design Temperature, psi (see Section II, Part D, Subpart 1, Tables 1A and 1B)
S_{AH}	= allowable design stress for hub material at (assembly condition) atmospheric temperature, psi (see Section II, Part D, Subpart 1, Tables 1A and 1B)
S_{OC}	= allowable design stress for clamp material at (service condition) Design Temperature, psi (see Section II, Part D, Subpart 1, Tables 1A and 1B)
S_{AC}	= allowable design stress for clamp material at (assembly condition) atmospheric temperature,

Page 448

	psi (see Section II, Part D, Subpart 1, Tables 1A and 1B)
S_1	= hub longitudinal stress on outside at hub neck, psi
S_2	= maximum Lame hoop stress at bore for hub neck section, psi
S_3	= hub axial shear stress (maximum) across the hub shoulder, psi
S_4	= hub radial shear stress (maximum) across the hub neck, psi
S_5	= clamp longitudinal stress at clamp body inner diameter, psi
S_6	= clamp tangential stress at clamp body outer diameter, psi
S_7	= shear stress (maximum) across clamp lips, psi
S_8	= clamp lug bending stress, psi
S_9	= effective bearing stress between clamp and hub, psi
T	= thickness of hub shoulder for design purposes, in. The hub shoulder ring is the ring with cross-sectional dimensions T by $(A - B)/2$.
W	= total design bolt load required for service or assembly, as may apply, lb
W_e	= total effective axial clamping preload on one clamp lip and hub shoulder (gasket seating or assembly), lb
	$= 1.571W/\tan(\phi + \mu)$
W_{m1}	= minimum required total bolt load for the service conditions, lb [see Q-1140(b)(1)]
W_{m2}	= minimum required total bolt load for gasket seating, lb [see Q-1140(b)(2)]

W_{m3}

= minimum required total bolt load for assembly, lb [see Q-1140(b)(3)]

X

= radial distance from inside surface of clamp body to the centroid of the clamp body, in.

=

$$\left[\left(\frac{C_w}{2} - \frac{C_t}{3} \right) C_t^2 - \frac{(C_w - C_g)}{2} l_c^2 \right] / A_c$$

y

= gasket or joint-contact surface unit seating load, psi (see Table XI-3221.1-1)

Z

= effective clamp-hub taper angle, deg. (for gasket seating and preload, $Z=\phi+\mu$; for operating, $Z=\phi-\mu$) [see Q-1140(b)(4)]

α

= hub-neck pipe transition taper, deg. (α shall not be greater than 45 deg.)

μ

= effective friction angle, deg.

ϕ

= clamp-hub taper angle, deg. (ϕ shall not exceed 35 deg.)

(a)

(b)

(c)

FIG. Q-1130-2 TYPICAL CLAMP LUG CONFIGURATIONS

FIG. Q-1130-2 TYPICAL CLAMP LUG CONFIGURATIONS

Q-1140 BOLT LOADS

(a) *General.* During assembly of the clamp connection, the design bolt load W is transferred via the clamp-hub taper angle to an axial load (effective clamp preload W_e). In addition, the effect of friction will cause W_e to be reduced for a given W . Friction effects can be reduced by lubrication or by jarring the clamps during assembly. An appropriate friction angle shall be established for both assembly and operating conditions.

(b) *Calculations.* In the design of the bolting for a clamp connection, complete calculations shall be made for three separate and independent sets of conditions which are defined as follows.

(1) The required bolt load for the service conditions W_{m1} shall be sufficient to:

(a) resist the hydrostatic end force H exerted by the maximum allowable working pressure on the area bounded by the diameter of gasket reaction; and

(b) maintain on the gasket or joint-contact surface, a compression load H_p which experience has shown to be sufficient to ensure a tight joint.

The minimum operating bolt load W_{m1} shall be determined in accordance with Eq. (1).

$$W_{m1} = 0.637 (H + H_p) \tan (\phi - \mu) \quad (1)$$

(1)

(2) Before a tight joint can be obtained, it is necessary to seat the gasket or joint-contact surface properly by applying a minimum initial load (under atmospheric temperature conditions without the presence of internal pressure), which is a function of the gasket material and the effective gasket area to be seated. The minimum initial bolt load required for gasket seating W_{m2} shall be determined in accordance with Eq. (2).

$$W_{m2} = 0.637 H_m \tan (\phi + \mu) \quad (2)$$

(2)

(3) To ensure proper preloading of the clamp connection against service conditions, an assembly bolt load W_{m3} shall be determined in accordance with Eq. (3).

$$W_{m3} = 0.637 (H + H_p) \tan (\phi + \mu) \quad (3)$$

(3)

(4) In Eq. (1) credit for friction is allowed based on clamp connection geometry and experience, but shall be limited to a value in which $(\phi + \mu)$ is equal to or greater than 5 deg. In Eqs. (2) and (3), friction shall be considered and be such that μ is equal to or greater than 5 deg. This will then satisfy the requirements of Q-1110(d).

Page 449

(5) The need for providing sufficient bolt load for either gasket seating in accordance with Eq. (2) or assembly in accordance with Eq. (3) will prevail on many low pressure designs and with facings and materials that require a high seating load where the service bolt load computed by Eq. (1) is insufficient to properly preload the connection.

(c) *Required Bolt Area.* The total cross-sectional area of bolting A_m required shall be the greater of the values for service conditions A_{m1} , gasket seating conditions A_{m2} , or assembly condition A_{m3} . Bending of the bolting due to nonparallel nut bearing surfaces shall be compensated for by use of a stress correction factor in bolt area calculations or by use of spherically seated nuts and/or washers.

(d) *Clamp Connection Design Bolt Load W .* The bolt load used in the design of the clamp connection shall be the values obtained from Eqs. (4) and (5).

For service conditions:

$$W = W_{m1} \quad (4)$$

(4)

For assembly conditions:

$$W = (A_m + A_b)S_a \quad (5)$$

(5)

Q-1150 HUB MOMENTS

In the calculation of hub stresses, the moment of a load acting on the hub is the product of the load and its moment arm. The moment arm is determined by the relative position of the effective hub-clamp reaction diameter with respect to that of the load producing the moment [see Fig. Q-1130-1, sketches (c) and (d)]. In addition to the load moments, additional reaction moments with relation to the hub shoulder ring centroid are considered to compensate for hub-to-pipe transition, radial pressure, and clamp radial equilibrating effects.

For the service conditions, the rotational hub moment M_O is the sum of six individual moments M_D, M_G, M_T, M_P, M_P , and M_R based on the design bolt load of Eq. (4) with moment arms as given in Fig. Q-1130-1.

For assembly, the rotational hub moment M_O is based on the design bolt load of Eq. (5) in which case

$$M_O = \frac{0.785 W(C - G)}{\tan(\phi + \mu)} \quad (6)$$

(6)

Q-1160 CALCULATION OF HUB STRESSES

The stresses in the hub shall be determined for both the service and the assembly conditions.

(a) The reaction moment M_H and reaction shear Q as defined in Q-1130 shall be calculated at the hub neck for rotational moment M_O

(b) Hub stresses are to be calculated from the following formulas:

Hub longitudinal stress

$$S_1 = f \left[\frac{PB^2}{4g_1(B + g_1)} + \frac{1.91 M_H}{g_1^2(B + g_1)} \right] \quad (7)$$

(7)

Hub hoop stress

$$S_2 = P \left(\frac{N^2 + B^2}{N^2 - B^2} \right) \quad (8)$$

(8)

Hub axial shear stress

$$S_3 = \frac{0.75 W}{T(B + 2g_1) \tan Z} \quad (9)$$

(9)

Hub radial shear stress

$$S_4 = \frac{0.477 Q}{g_1 (B + g_1)} \quad (10)$$

(10)

Q-1170 CALCULATION OF CLAMP STRESSES

The stresses in the clamp shall be determined for both the service and the assembly conditions. Clamp stresses are to be calculated from the following equations:

Page 450

Clamp longitudinal stress

$$S_5 = \frac{W}{2C(\tan Z)} \left[\frac{1}{C_t} + \frac{3(C_t + 2l_m)}{C_t^2} \right] \quad (11)$$

(11)

Clamp tangential stress

$$S_6 = \frac{W}{2} \left[\frac{1}{A_c} + \frac{|e_b|(C_t - X)}{I_c} \right] \quad (12)$$

(12)

Clamp lip shear stress

$$S_7 = \frac{1.5 W}{(C_w - C_g) C \tan Z} \quad (13)$$

(13)

Clamp lug bending stress

$$S_8 = 3 W \frac{L_a}{L_w L_h^2} \quad (14)$$

(14)

In addition, a bearing stress calculation is to be made from Eq. (15) for either the clamp or hub.

$$S_9 = \frac{W}{(A - C_i) C \tan Z} \quad (15)$$

(15)

**TABLE Q-1180-1
ALLOWABLE DESIGN STRESS FOR CLAMP
CONNECTIONS**

Stress Category	Allowable Stress
S_1	$1.5 S_{OH}$ or $1.5 S_{AH}$
S_2	S_{OH}
S_3	$0.8 S_{OH}$ or $0.8 S_{AH}$
S_4	$0.8 S_{OH}$ or $0.8 S_{AH}$
S_5	$1.5 S_{OC}$ or $1.5 S_{AC}$
S_6	$1.5 S_{OC}$ or $1.5 S_{AC}$
S_7	$0.8 S_{OC}$ or $0.8 S_{AC}$
S_8	S_{OC} or S_{AC}
S_9	(1)

NOTE:

(1) 1.6 times the lower of the allowable stresses for hub material (S_{OH} , S_{AH}) and clamp material (S_{OC} , S_{AC}).

Q-1180 ALLOWABLE DESIGN STRESS FOR CLAMP CONNECTIONS

Table Q-1180-1 gives the allowable stresses that are to be used with the equations of Q-1160 and Q-1170.

APPENDIX R DETERMINATION OF PERMISSIBLE LOWEST SERVICE METAL TEMPERATURE FROM T_{NDT} FOR CLASSES 2 AND MC CONSTRUCTION

Page 451

ARTICLE R-1000 DETERMINATION OF PERMISSIBLE LOWEST SERVICE METAL TEMPERATURE FROM T_{NDT} FOR CLASSES 2 AND MC CONSTRUCTION

R-1100 INTRODUCTION

R-1110 Scope

These rules provide the method for determining the permissible lowest service metal temperatures for materials having nil-ductility transition temperatures (T_{NDT}) determined in accordance with NC- or NE-2311(a)(8) or NC- or NE-2331(a)(2).

R-1200 DETERMINATION OF PERMISSIBLE LOWEST SERVICE METAL TEMPERATURE

The permissible lowest service metal temperature is defined as:

$$T_{NDT} + A$$

where T_{NDT} is determined in accordance with NC- or NE-2311(a)(8) or NC- or NE-2331(a)(2), and A is determined from Fig. R-1200-1 for the thickness of the material.

R-1210 Material Acceptability

For the material to be acceptable, the permissible lowest service metal temperature shall not be higher than the specified lowest service metal temperature.

APPENDIX S PUMP SHAFT DESIGN METHODS

Page 455

ARTICLE S-1000 PUMP SHAFT DESIGN METHODS

S-1100 INTRODUCTION

(a) This Appendix provides guidelines for the design and evaluation of shafts for Section III nuclear pumps. They include suggestions for the loads to be considered and the method for arriving at a design that will sustain these loads for the life of the pump.

(b) The method presented is not intended to exclude other methods which may be equally satisfactory. Experience and expertise will be factors in determining the best method. In the final analysis the skill and judgement of the designer determine the quality of the design.

S-1200 SCOPE

The guidelines presented are intended to cover the design of pump shafts, including rigid couplings, up to, but not including, separable parts which attach the shaft to the driver.

S-1300 DESIGN REQUIREMENTS

S-1310 DESIGN METHODS

The design rules presented in this section are provided as guidance to the designer of pump shafts. Alternative design methods may be used based on the pump manufacturer's experience with pumps in similar service.

S-1320 OPERATING CONDITIONS

Pump shaft assemblies are subject to combinations of steady state and variable or transient loads. These loads include torsional, lateral, bending, axial, and thermal components. They may occur as a result of power input, hydraulically imposed forces, static or dynamic unbalance, rotating element runout, internal misalignment, thermal distortion, system and component vibration, and resonance. External system applied loads, such as seismic and other loads associated with A, B, C, and D Service Level Loadings must also be considered.

S-1400 RESPONSIBILITY

(a) *Owner's Responsibility.* It shall be the responsibility of the Owner or his designee to include in the Design Specification all external forces and operating conditions that may have an effect on the operability of the pump shaft.

(b) *Pump Designer Responsibility.* It is the responsibility of the pump Designer to include in the evaluation the specified pump loads and identify the type and magnitude of the internal operating loads on the shaft assembly.

S-1500 OPERATING LOADS

S-1501

In establishing maximum shaft operating loads, the design should take into account plant service that the pump will experience and external loads associated with these conditions. Other forms of off-normal operating loadings may include inservice testing, inadvertent starting and stopping, loss of coolant accident, etc.

S-1502

Thermal loads shall be considered as one of the internal operating loads.

S-1503 Off-Normal Operating Loads

The maximum steady state and transient loads will usually occur in the pump when it is operating away from its best efficiency point. Typically it will be the combination of loads producing stresses at regions of high stress concentration that may result in high cycle

Page 458

fatigue failures of shafts. The very nature of these loads makes it difficult to quantify them and in some cases a bounding estimate must be made. Examples of load sources include low flow recirculation, flow separation, and other hydraulic instabilities which cause radial and axial alternating or transient loads on the shaft. Lacking a thorough understanding of these loads, conservative design practices based on years of operating experience must be used to insure successful design of pump shafts.

FIG. S-1600-1 TYPICAL CENTRIFUGAL PUMP SHAFT FAILURE LOCATIONS

S-1600 SHAFT FAILURE MODES

Shaft failures usually occur at points of high stress concentration or structural discontinuities. The most common locations of shaft failures are threaded regions, shaft grooves, shoulders, keyways, couplings, and collars (see Fig. S-1600-1). Areas susceptible to erosion/corrosion, stress corrosion cracking, thermal transients, and steep temperature gradients are also possible locations for shaft failure.

Page 460

ARTICLE S-2000 DESIGN PROCEDURE

Any method of evaluation (analytical or experimental) which can be substantiated by data from pumps in service, experiencing conditions similar to the specified operating limits, may be used.

S-2100 CRITICAL SPEEDS

The evaluation shall address both torsional and lateral, and where applicable, axial critical speeds, shaft deflections, and stresses. Critical speeds and shaft deflections shall be such as to avoid any difficulties for the specified range of the design and operating conditions. The actual percentage difference between critical and operating speeds shall take account of the method of determination of critical speed. The percentage difference between stress allowed and calculated shall also take account of the accuracy of the design and the analysis method.

S-2200 MAXIMUM TORSIONAL LOAD

The maximum torsional load shall be defined. The maximum torsional shear stress for this load (stress resulting from this load without application of concentration factors) shall be based on design experience or experimental evidence for the particular class of pump involved. The maximum driver horsepower may determine the maximum torsional loading for units with short shafts (typical of pump types A, B, and C). The motor startup torque may determine the maximum torsional load for pumps with relatively long shafts (typical of type L pumps). Torsional alternating or transient loads shall be considered if applicable.

S-2300 SHAFT EVALUATION

The flow chart, Fig. S-2300-1, outlines a procedure for evaluation of pump shafts to meet load requirements. This procedure establishes a basic sizing criterion as well as a detailed fatigue evaluation method.

The basic shaft sizing criterion is based on maximum shear stress and conservative cyclic loading factors. These fatigue factors include an evaluation of the endurance limit of the unnotched and polished test specimen reverse bending test data in air (S_e), which in the absence of specified data can be approximated as:

$$S_e = 0.5S_u$$

This polished specimen test endurance limit is then factored for the product of reduction factors that account for such items as environment, reliability, size, finish, duty cycles, etc., which is conservatively estimated as $1/3$. Consequently, this corrected material endurance limit stress can be represented as:

$$S'_e = \frac{1}{K_{\text{total}}} \cdot \frac{S_e}{3}$$

where the terms used on the chart, Fig. S-2300-1, are as follows:

K_{total}	= stress concentration factors. An initial value of 6.0 is suggested where reasonable stress riser control is exercised. Higher values may be required for designs with severe discontinuities (eg., small fillet radii relative to shaft diameter). Lower values may be used if justified by design methods and/or testing that accounts for the specific shaft discontinuities under consideration. Notch sensitivity values, when available, may be used. For additional information, see ANSI/ASME B106.1M-1985.
S_a	= alternating axial stress
S_b	= alternating component of the shaft bending stress
S_e	= material endurance limit
S'_e	= design endurance limit
S_s	= maximum shear stress
S_{ss}	= material allowable shear stress

Page 461

Page 462

	= $S_y/3$ unless higher values are justified through specified shear test data
S_u	= material ultimate strength at design temperature
S_y	= material yield stress at design temperature
U_t	= summation of usage cycles. Each usage cycle shall be determined as the ratio of the maximum alternating stress in

determined as the ratio of the maximum alternating stress in the shaft divided by the design fatigue stress of the material for that number of cycles. U_T will be determined by summing all of the above ratios.

FIG. S-2300-1 STEPS IN THE DESIGN OF A PUMP SHAFT

S-2400 OTHER CONSIDERATIONS

The fatigue life of a shaft is not always the limiting factor in its design. The effect of misalignment and deflection of a shaft on the performance of support bearings, seals, and couplings as well as on other key power transmission components must also be taken into account. Shafts can be strong enough to meet fatigue life requirements, yet not stiff enough to satisfy natural frequency and operational requirements.

SEC III D1 NMA APP T

APPENDIX T RECOMMENDED TOLERANCES FOR RECONCILIATION OF PIPING SYSTEMS

Page 463

ARTICLE T-1000 RECOMMENDED TOLERANCES FOR RECONCILIATION OF PIPING SYSTEMS

T-1100 INTRODUCTION

The building structure and major components of a power plant are constructed according to rules that permit varied tolerances. Since piping system installation follows construction of the building and installation of the major components, the piping systems must be permitted to vary within the space allotted to them. In addition, a large number of systems are often installed in a limited space. Interferences often occur and changes within Installation Tolerances may be used to eliminate the interference. The tolerances provided in this Appendix bridge the gap between the exactness associated with a design by analysis, and a practical and acceptable installation.

The basis for the tolerances and guidance in this Appendix was developed by the PVRC Technical Committee on Piping Systems.¹ Additional guidance on implementation of these tolerances has been published by EPRI.²

T-1110 SCOPE

This Appendix provides recommended tolerances and methods for satisfying the requirements of NCA-3554, "Modification of Documents and Reconciliation With Design Report" for piping systems designed to the rules of NB-, NC-, or ND-3600. This Appendix provides:

- (a) identification of dimensions and weights significant to the piping stress analysis; and
- (b) acceptable tolerances for these dimensions and weights such that if piping is installed within these tolerances, the reconciliation is accomplished.

¹ "Technical Position on Piping Installation Tolerances," *Welding Research Council Bulletin* 316, July 1986.

² "Guidelines for Piping System Reconciliation" (NCIG-05, Revision 1), *Electric Power Research Institute, EPRI-5639*, May 1988.

These tolerances have been established such that their effect on the accuracy of analysis results is minimal and is consistent with accepted practices and the use of tolerances in the Code. These tolerances are applicable to most situations; however, specific situations where more restrictive tolerances may be needed are identified.

The tolerances in this Appendix are applicable to piping systems where conventional seismic analysis methods were used for the original design, i.e., modal response spectrum analysis methods. For piping systems where seismic analysis methods that are significantly more sensitive to the tolerances were used in the original design (i.e., seismic time history analysis methods), the Designer shall review the applicability of these tolerances and establish more stringent guidelines if necessary. Further, this Appendix shall be restricted to piping systems analyzed using linear elastic methods.

This Appendix does not relieve the Designer of responsibility for consideration of other unique situations where more restrictive tolerances may be required to satisfy the intent of the design bases or the Code.

Installation Tolerances more restrictive than the Total Tolerances recommended in this Appendix may be specified. Less restrictive tolerances may be specified when engineering justification is provided to demonstrate that the design requirements have been satisfied.

Tolerances for complete, installed piping are addressed. Tolerances provided for manufacturing or fabricating the individual items or subassemblies that make up piping systems are not addressed, but the effect of these tolerances on the as-installed condition shall be within the Total Tolerance. Other design and construction areas which may be included in reconciliation such as design or operating conditions, support details, and gaps are not addressed.

Tolerances for support erection, including length and orientation of individual members and pipe location on the support, are specified in Appendix K.

Page 466

T-1120 TERMS RELATED TO RECONCILIATION

Definitions of terms used in this Appendix are given in the following paragraphs.

T-1121 Nominal Dimension

This is the dimension which provides configuration and/or spatial information on piping drawings within specified tolerances.

T-1122 As-Analyzed Configuration

This is the configuration of piping components and supports, defined by nominal sizes, weights, cross section properties, and dimensions, which forms the basis for the piping stress analysis. In the case of piping systems which are qualified by simplified rules, the design drawings for the systems are considered as the As-Analyzed Configuration.

T-1123 Critical-to-Design (CTD) Dimension

A dimension that must be satisfied, within a specified tolerance, in order for the piping stress analysis to remain valid. These dimensions define the relative configuration of the piping. They may also include dimensions which define the global or spatial position of the piping.

Examples of CTD dimensions are: the location of a pipe support relative to in-line pipe components such as valves, anchors, and other supports; the orientation of the pipe support center line relative to the pipe center line; length of pipe runs; and spacing between supports.

T-1124 Fit/Clearance (F/C) Dimension

This is a dimension that is specified to provide reasonable assurance that the piping fits into the allocated building space. These dimensions define the global position of the piping in three-dimensional space and deviations from these dimensions do not have a significant effect on the validity of the piping stress analysis. Examples of F/C dimensions are the locating dimensions of pipe center lines from column lines, walls, and floors. However, dimensions defining clearance required to allow thermal expansion or to protect critical components from adverse interaction due to dynamic (earthquake) loads are CTD dimensions.

T-1125 As-Built Documents

These are the drawings, sketches, or other documents which define the as-installed piping configuration (nominal dimensions and tolerances) and which have been reconciled with the stress analysis.

T-1126 Installation Tolerance

This is the specified acceptable departure from nominal piping dimensions, support locations and orientations, and

component weights to be used during installation to provide for practical installation limitations. Installation Tolerances for CTD dimensions shall be less than or equal to the corresponding Total Tolerances.

T-1127 Total Tolerance

This is the maximum allowable departure between corresponding as-built and as-analyzed CTD piping dimensions, support locations and orientations, and component weights for the piping stress analysis to be applicable. The Total Tolerance is applicable only to CTD dimensions since F/C dimensions are not critical to the stress analysis. Acceptable Total Tolerances are provided in T-1200.

T-1130 MEASUREMENT ACCURACY

Measurements of the as-built configuration for use in reconciliation shall be made using methods capable of producing accuracy to the nearest inch for linear dimensions and to the nearest 2 deg. for angular dimensions (Fig. T-1213-1 shows examples of angular dimensions).

T-1140 EVALUATION OF OUT-OF-TOTAL TOLERANCE CONDITIONS

CTD values that exceed Total Tolerances shall be recorded and evaluated to assure the design bases, including the applicable design code, have been satisfied. This evaluation may be made using engineering judgment, simplified models, or by reanalyzing the complete original model. The objective should be to determine if the condition being evaluated had any significant effect on the response of the piping systems to the design loadings. The use of engineering judgment shall be documented with the technical reasoning described so that a technically qualified third party reviewer will understand how the evaluation was justified. The documentation requirements for evaluation based on

Page 467

Page 468

engineering judgment shall be consistent with other engineering calculations.

FIG. T-1213-1 ILLUSTRATIONS OF ANGULAR DIMENSIONS — PIPE LEGS, VALVES, SUPPORTS, BENDS

FIG. T-1213-1 ILLUSTRATIONS OF ANGULAR DIMENSIONS - PIPE LEGS, VALVES, SUPPORTS, BENDS

If it is determined that there is no significant effect, then the original analysis remains valid and the results (stress summaries, support design loads, etc.) need not be revised. If changes are found to be significant, then the affected results shall be revised.

T-1200 TOTAL TOLERANCES

T-1210 GENERAL

The Total Tolerances are given for the reconciliation of the piping stress analysis in terms of the maximum allowable plus or minus departure between the as-analyzed (nominal) value and the as-built value. These tolerances should not be used to circumvent specific requirements established by the Design or Installation Specification nor other applicable material or fabrication standards.

As-built piping systems that conform with the piping stress analysis within the Total Tolerances are acceptable and evaluation of the as-built condition is not required.

T-1211 Altering Relative Position

Tolerances shall not be applied in such a manner that would result in alteration of the relative position of piping components and supports. For example, supports shall not be moved across valves, tees, elbows, etc. In no case shall the permissible location change the directions of a support or its function.

T-1212 Independence

The tolerances given are independent of each other and are not interrelated to position of adjacent items except as noted in T-1211. Each tolerance may be applied independently of any other.

T-1213 Methods of Dimensioning

Examples of angular dimensions are shown in Fig. T-1213-1. Two common methods of dimensioning piping installation are shown in Fig. T-1213-2. Either method or some combination of these methods are usually used on the Design Drawings. The chain method references a dimension to the adjacent dimensions. The common point method references a number of dimensions to a common base. All measurements should be rounded off to the nearest inch for linear dimensions and the nearest 2 deg. for angular dimensions.

T-1220 PIPING CONFIGURATION TOLERANCES

T-1221 Center Line Lengths

Center line length to fittings, flanges, valves, and piping specialties including branch line piping shall be within the tolerance specified below. (Locations of branch connections on the run pipe are not included. See T-1222.)

Specified Nominal Dimension (Feet)	± Total Tolerance (Inches)
0 to <5	3
5 to <10	6
10 to <15	9
15 to <20	12
20 to <25	15
25 to <30	18
30 to <35	21
35 and over	24

NOTE: The 3 in. tolerance for nominal dimensions of 0 to less than 5 ft may not be applicable in all cases. For example,

cantilevered vents and drains, relief valve inlet and outlet piping, and instrument piping near the connection to the process piping are cases where more restrictive tolerances may be needed. If so, they shall be specified on the design documents.

When common point dimensions (see Fig. T-1213-2) are used, the tolerances along the pipe center line are to be applied to each pipe leg, i.e., piping between changes in direction. There may be cases where the nominal dimensions must be determined from the difference in common point dimensions for the ends of the pipe leg.

T-1222 Center Line Location of Branch Connections (Relative to Run)

(a) This section applies to branch connections independent of the connection detail or type of fitting used.

(b) The location of branches for branch/run size combinations indicated by an asterisk (*) in Table T-1222-1 have no design related tolerance restrictions except when the stress intensification factor (SIF) on the run pipe exceeds 1.0, in which case the maximum tolerance is ± 2 ft 0 in. (610 mm) and the requirements of (d) shall be satisfied.

(c) The location of branches for the branch/run size combinations without an asterisk (*) in Table T-1222-1 (including sizes not listed in the table) have the same tolerance as in T-1221.

(d) For all branch/run size combinations, changes in location of the branch connection that exceed 2 ft (610 mm) shall be approved by the Designer and should not

(1) change the flow path defined on the piping system diagram;

(2) affect system functional flow and pressure characteristics, such as branch connections used for differential

TABLE T-1222-1 BRANCH/RUN SIZE COMBINATIONS

(3) be allowed without considering the effect of run pipe movement on the branch pipe. (Not significant if the tolerances of T-1221 are satisfied.)

T-1223 Angular Deviation of Pipe Center Line

Angular deviation of pipe center line from theoretical center line is limited to ± 10 deg. See Fig. T-1213-1, Rolled Ells ("B°") and Bends; Nonstandard Ells ("C°").

T-1224 Angular Tolerance on Power Operated Valves

Angular tolerance on power operated valves over NPS 2 (Nominal Pipe Size) is limited to ± 15 deg. See Fig. T-1213-1, Valves ("D°"). For power operated valves NPS 2 and smaller, the angular tolerance of ± 15 deg. applies only when the weight of the valve operator equals or is less than the valve analyzed weight. When the weight of the valve operator exceeds the valve's analyzed weight for an NPS 2 (DN 50) or smaller valve, the angular tolerance is not provided in this Appendix. There are no CTD restrictions on angular orientation of manually operated valves.

T-1230 PIPING SUPPORT LOCATION/ORIENTATION TOLERANCES

The tolerance provided as piping support tolerances assume the support is the specified type and rating. The support type shall not be changed without approval of the Designer.

These tolerances are applicable to the reconciliation of the piping stress analysis. They are not applicable for the reconciliation of the pipe support design.

T-1231 Location of Supports

Tolerances on the location of supports, anchors, and restraints along the pipe center line of the horizontal or vertical straight runs that do not contain significant concentrated weight are:

Pipe Size	Tolerance
NPS 2 and smaller	6 in.
NPS 2½ and larger	One pipe diameter or 12 in., whichever is greater

T-1232 Location of the First Support on Either Side of Spans That Contain Concentrated Weights

Tolerances on the location of the first support or restraint on either side of spans that contain concentrated weights such as valves, flanges, risers, fittings, bends, or other concentrated loads are:

Pipe Size	Tolerance
NPS 12 and smaller	Smaller of 3 pipe diameters or 12 in.
Larger than NPS 12	One pipe diameter

These tolerances may not be applicable to the first restraint adjacent to a bend, which is oriented in the plane of the bend, when the piping is subjected to waterhammer, steamhammer, or relief valve discharge loading. In these cases, if more restrictive tolerances are needed they must be specified on the design documents.

T-1233 Location of the First Support From Rotating Equipment Nozzles

Tolerances for the location of the first support or restraint in each direction from rotating equipment nozzles are:

Pipe Size	Tolerance
NPS 2 and smaller	3 in.

NPS 2½ and larger

One-half pipe diameter or 6 in., whichever is greater

T-1234 Snubbers

The location of snubbers with axis coincident to the pipe leg center line is not a critical dimension. However, snubbers with tolerances greater than those of T-1231 should be approved by the Designer who must assure they are not affected by the anticipated thermal movements.

T-1235 Angular Orientation of Supports

The tolerance for the angular orientation of supports is ± 5 deg. [See Fig. T-1213-1, Supports ("E").] The angular tolerance may be increased to ± 10 deg. if this value plus the angularity change from thermal expansion of the system does not exceed functional limitations established by the support manufacturer and the Designer assures that any increased loadings on the connection are compatible with the design.

T-1240 WEIGHT TOLERANCES

T-1241 General

Tolerances on both uniformly distributed weights and concentrated weights are included in this Appendix. These tolerances do not imply that components should be weighed, but provide for reconciliation of weight changes identified in the design process. As a practical matter, the concentrated weight of items is a concern primarily for valves and other in-line components of significant weight, but particularly power operated valves. Changes to the distributed weight of insulation systems and other piping items should also be considered.

T-1242 Uniformly Distributed Weight

The uniformly distributed weight for the piping system may vary by $\pm 20\%$ from the as-analyzed weight.

This weight tolerance may need to be reduced for piping primarily supported by constant force supports or springs.

T-1243 Concentrated Weight

Concentrated weights of in-line items such as valves may vary by the greater of $\pm 20\%$ of the analyzed weight or 20 lb (9 kg).

SEC III D1 NMA APP U

APPENDIX U RULES FOR PUMP INTERNALS

Page 473

U-1000 RULES FOR PUMP INTERNALS

U-1100 INTRODUCTION

U-1110 SCOPE

These rules apply to materials, fabrication and examination of internal items for Classes 1, 2 and 3 pumps. Pump internal items are those parts other than pump cases, inlets and outlets, covers clamping rings, seal housings, related bolting and other items as covered in Subsections NB, NC, and ND.

U-1120 CATEGORIES

Category as set forth in Table U-1600-1 is the grouping of various pump internal items for the purpose of applying the rules of this Appendix. Categories for typical pump types are shown in Figs. U-1500-1 through U-1500-7. The figures are not to scale, and are not intended to convey any preference for pump type or design, but are provided as a guide to the manufacturer to identify the various internal items of a pump for categorization. In determining categories for items of pump types not specifically illustrated, a pump or pump detail which is most nearly representative shall apply. Categories 1 and 2 are pressure retaining items presently covered by Subsections NB, NC and ND. Categories 3 through 6 are pump internal items which may be constructed in accordance with this Appendix except that Material Manufacturers and/or Material Suppliers for Category 3 through 6 items are not required to comply with NCA-3800. Material which forms an integral welded extension to Category 1 material in Fig. U-1500-1, items 1-5, may be classified as Category 4 or 5 material when it serves a nonpressure-retaining function and its structural effect is considered in the design of the Category 1 material. For use in Class 1, 2, and 3 pumps the extension material shall satisfy the requirements of NB-2300 NC-2300, or ND-2300.

U-1200 GENERAL REQUIREMENTS

U-1210 RESPONSIBILITIES AND DUTIES

It is the responsibility of the Certificate Holder manufacturing pumps to assign each item of a pump to the proper category and to indicate the categories in a report or on a drawing.

U-1220 CODE STAMPING

Code symbol stamping is not required for pump internal items.

U-1300 MATERIALS

U-1310 GENERAL REQUIREMENTS FOR MATERIAL

U-1311 Scope of Principal Terms Employed

The term *materials* as used in this Appendix applies to those items produced to material specifications permitted by Section III, Division 1, and/or other material permitted by this Appendix.

U-1312 Permitted Material Specifications

(a) Materials used for Category 3 and 4 items shall conform to the requirements of one of the specifications for materials given in Table U-1610-1 of this Appendix for Class 1, 2 and 3 pumps; materials listed in Section II, Part D, Table 2A for Class 1 and 2 pumps; materials listed in Table 2A for Class 2 pumps; or materials listed in Table 1A for Class 3 pumps; and to the special requirements of this Appendix which apply to the item for which the material is used.

(b) Category 5 and 6 items may be made from any material suitable for the intended service.

(c) The Certificate Holder manufacturing pumps shall provide a list which identifies the material used for

Page 476

each Category 3, 4, 5 or 6 item. This list may be a bill of materials or a separate list.

(d) Where the tensile strength, yield strength, tempering temperature or aging temperature listed in Table U-1610-1 differ from the requirements of the material specification, the minimum requirements listed in Table U-1610-1 shall apply.

U-1313 Special Requirements Conflicting With Permitted Material Specifications

(a) Special requirements stipulated in this Appendix shall apply in lieu of the requirements of the material specifications wherever the special requirements conflict with the material specification requirements. Where the special requirements include an examination, test, or treatment which is also required by the material specification, the examination, test, or treatment need be performed only once. Any required nondestructive examinations shall be performed as specified in para. U-1430 Any examination, repair, test, or treatment required by the material specification or this Appendix may be performed by the Material Manufacturer, Material Supplier, or the Certificate Holder manufacturing pumps. The Material Manufacturer or Material Supplier shall obtain approval from the Certificate Holder manufacturing pumps for the weld

repair of materials (see para. U-1440).

(b) For materials listed in Table U-1610-1 for Category 3 and 4 items, the tensile test requirements of the material specification may be performed on representative samples of each heat of material used, for each specified heat treatment. The tensile strength and yield strength results shall satisfy the specified values *and be below the maximum specified values listed in Table U-1610-1*. Where the material will be used to fabricate various item sizes in different heat treated thicknesses, the manufacturer shall assure himself that the heat treatment specified will be effective for the entire size range.

U-1314 Certification of Materials

(a) *Certification by Material Manufacturer.* The Material Manufacturer shall provide a Certified Material Test Report for Category 3 items and Category 4, Class 1 impellers, including all welding and brazing materials used on these items. The Material Manufacturer shall certify that the contents of the report are correct and accurate, and that all operations performed by him or his subcontractors are in compliance with the requirements of the material specification and this Appendix. Alternatively, the Material Manufacturer shall provide a Certified Material Test Report for operations he performed and at least one Certified Material Test Report from each of his subcontractors for operations they performed. Chemical analysis, tests, examinations, and heat treatments required by the material specification that were not performed shall be listed on the Certified Material Test Report. A Material Manufacturer's Certificate of Compliance with the material specification, grade, class, and heat treated condition, as applicable, may be provided in lieu of a Certified Material Test Report for material used for pumps with inlet connections 2 in. nominal pipe size and less, and bolting 1 in. nominal diameter and less. Material identification including any marking code (see para. U-1316) shall be described in the Certified Material Test Report or Certificate of Compliance as applicable.

(b) *Certification by Material Supplier.* The Material Supplier who completes any operation not performed by the Material Manufacturer shall provide a Certified Material Test Report for all operations performed by him. This certification affirms that the contents of the report are correct and accurate, and that all test results and operations performed by him or his subcontractors are in compliance with the material specification and the applicable material requirements of this Section as designated by the purchaser.

(c) Certified Material Test Reports or Material Manufacturer or Material Supplier Certificates of Compliance are not required for Category 5 and 6 items.

U-1315 Welding and Brazing Materials

All welding and brazing materials used on Category 3 and 4 items shall meet the requirements of NB-2400, NC-2400, or ND-2400, as applicable.

U-1316 Material Identification

U-1316.1 Class 1 and 2 Pump Items

(a) The identification of Materials for Category 3 items used for Class 1 and 2 pumps shall consist of marking or tagging the material with the applicable specification number, grade, heat number or heat code, and any additional marking required to facilitate traceability of the reports of the results of all tests and examinations performed on the material, except that heat number identification is not required for pumps with inlet connections 2 in. nominal pipe size (DN 50) and less. Alternatively, a marking symbol and/or code may be used which identifies the material with the Materials Certification and such symbol and/or code shall be explained in the certificate (see para. U-1314).

Page 477

For identification and marking during fabrication by the Pump Manufacturer, see para. U-1420.

(b) The identification of Materials for Category 4 items used for Class 1 and 2 pumps shall consist of marking or tagging the material or its container in accordance with the marking requirements of the applicable material specification. Category 5 items shall be identified as set forth in the Manufacturer's Quality System Program.

(c) Materials may be marked by any method which will not result in any harmful contamination or sharp discontinuities. Stamping, when used, shall be done with blunt-nosed-continuous or blunt-nosed-interrupted-dot die

stamps.

U-1316.2 Class 3 Pump Items.

The identification of materials for Category 3 through 5 items used for Class 3 pumps shall consist of marking the material or its container in accordance with the requirements of the Manufacturer's Quality System Program.

U-1316.3 Welding and Brazing Material Identification.

Welding and brazing materials shall be clearly identified by legible marking on the package or container *so that they are identifiable as acceptable material until the material is actually consumed in the process.*

U-1320 FRACTURE TOUGHNESS REQUIREMENTS FOR CATEGORY 3 MATERIALS

U-1321 Materials to Be Impact Tested

Impact tested specimens shall be representative of the final heat treatment of the finished part.

U-1321.1 Materials for Which Impact Testing Is Required.

Materials for Category 3 items for Class 1 pumps, and for Class 2 and 3 pumps when required by the Design Specification, shall be impact tested in accordance with the requirements of para. U-1320 except that the following materials do not require impact testing:

- (a) all thickness of materials for pumps with a nominal inlet pipe size 6 in. (152 mm) diameter and smaller;
- (b) materials for pumps with all pipe connections of $\frac{5}{8}$ in. (16 mm) nominal pipe wall thickness and less;
- (c) materials with a nominal section thickness of $\frac{5}{8}$ in. (16 mm) and less;
- (d) bars with a nominal cross-sectional area of 1 sq in. (645 mm²) and less;
- (e) austenitic stainless steels;
- (f) nonferrous materials.

U-1321.2 Impact Test Procedure

U-1321.2.1 Charpy V-Notch Tests.

The Charpy V-Notch Test shall be performed in accordance with SA-370. Specimens shall be in accordance with SA-370, Fig. 11, Type A. A test shall consist of a set of 3 full-size 10 × 10 mm specimens. The test temperature and lateral expansion shall be reported in the Certified Material Test Report.

U-1321.2.2 Location and Orientation of Test Specimens.

Impact test specimens shall be removed from the locations and orientations specified by the material specification for tensile test specimens in each product form.

U-1321.2.3 Test Requirements and Acceptance Standards.

Three Charpy V-Notch specimens shall be tested at a temperature equal to or lower than the lowest service temperature. All three specimens shall meet or exceed 15 mils lateral expansion (0.015 in.) (0.38 mm). Lowest service temperature is the minimum temperature of the fluid retained by the pump. The lowest service temperature shall be specified in the Design Specification.

U-1321.2.4 Retests.

One retest at the same temperature may be conducted provided:

- (a) not more than one specimen per test is below the minimum requirements; and
- (b) the specimen not meeting the minimum requirements is not lower than 5 mils (0.13 mm) below the specified requirements.

U-1400 FABRICATION REQUIREMENTS

Category 3 through 5 items shall be fabricated in accordance with the requirements of para. U-1400 and shall be manufactured from materials which meet the requirements of para. U-1300.

U-1410 CERTIFICATION OF MATERIALS AND FABRICATION BY PUMP MANUFACTURER

The pump manufacturer shall provide certification that all treatments, tests, repairs, or examinations performed on pump items are in compliance with the requirements of this Appendix. Reports of all required treatments and the results of all required tests, repairs, and examinations performed shall be maintained in accordance with NCA-3867.4 or NCA-4134.17.

Page 478

U-1420 MATERIAL IDENTIFICATION

Material for Category 3 and 4 items for Class 1 and 2 pumps shall carry identification markings, *including heat treatment grade either* directly on the item or on a separate tag that accompanies the item, which will be *maintained during and after assembly*.

U-1430 EXAMINATION OF MATERIALS

Bars and forgings for Category 3 pump shafting for Class 1 pumps, shall be ultrasonically examined in accordance with NB-2542 and NB-2547. Materials for Class 1 pumps, Category 3 items and Category 4 impellers for Class 1 pumps shall be examined on all external and accessible internal surfaces by the magnetic particle or liquid penetrant method in accordance with Section V. The examination may be performed by the Material Manufacturer, Material Supplier, or the pump manufacturer (see para. U-1313). Acceptance standards for magnetic particle and/or liquid penetrant examination shall be as follows.

- (a) Only indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant.
- (b) The following relevant indications are unacceptable:
 - (1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for materials less than $\frac{5}{8}$ in. (16 mm) thick; greater than $\frac{1}{8}$ in. (3.2 mm) long for materials from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick; and $\frac{3}{16}$ in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;
 - (2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;
 - (3) four or more indications greater than $\frac{1}{16}$ in. (1.6 mm) in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;
 - (4) ten or more indications greater than $\frac{1}{16}$ in. (1.6 mm) in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated;
 - (5) linear nonaxial indications.

Materials for Category 4 and 5 items for Class 1 pumps and for Category 3, 4, and 5 items for Class 2 and 3 pumps shall be examined in accordance with the material specification. When Category 4 or 5 material forms an integral or welded extensions to Category 1 material (see para. U-1120), the examination required for the Category 4 or 5 portion shall be in accordance with this Appendix. In addition, the requirements for the examination of the Category 1 portion shall be applied for a distance of at least $2t$ (t is thickness of the Category 4 or 5 material) from the Category 1 boundary as defined by the pump designer.

U-1431

U-1431 Time of Examination

Magnetic particle or liquid penetrant examination shall be performed in the finished conditions, *after all heat treatment operations and postweld heat treatment*, except that threaded items may be examined prior to threading. Examinations shall be performed prior to any coating or plating. Lapping of seating surfaces to reduce leakage or lapping of bearing surfaces shall not require reexamination.

U-1432 Elimination of Surface Defects

(a) Unacceptable surface defects shall be removed by grinding or machining, provided:

- (1) the remaining thickness of the section is not reduced below the minimum required by the design;
 - (2) the depression, after grinding or machining, is blended uniformly into the surrounding surface and the depression does not affect the function of the item;
 - (3) after grinding or machining, the area is examined by the method which originally disclosed the defect to assure that the defect has been removed or the indication reduced to an acceptable size.
- (b) If grinding or machining reduces the thickness of the section below the minimum required by the design, the item may be repaired and returned to an acceptable size.

U-1440 REPAIR BY WELDING OF CATEGORY 3, 4, AND 5 PUMP ITEMS

(a) Category 3, 4 and 5 items for Class 1, 2 and 3 pumps may be repaired by welding using the provisions of Section IX for materials in Table U-1610-1 with assigned P-numbers provided the requirements of the following subparagraphs are met.

(b) Until such time as P-numbers are assigned, welding of those materials without P-numbers shall be separately qualified as required by Section IX.

(c) Bolts, studs, nuts, and material for which welding is prohibited by Note 2 of Table U-1610-1 shall not be repair welded.

Page 479

U-1441 Defect Removal

The defect shall be removed or reduced to an acceptable size by suitable mechanical or thermal cutting or gouging methods and the cavity prepared for repair.

U-1442 Qualification of Welding Procedures and Welders

(a) When impact tests of Category 3 items are required, the impact testing requirements of para. U-1321.2.3 shall be met in the heat affected zone regardless of filler metal used and in the weld metal for all material except austenitic and nonferrous filler metal.

(b) Except as permitted in (c) below, the welding procedure and welders or welding operators shall be qualified in accordance with Section IX.

(c) Heat-treated materials listed in Table U-1610-1 which are not capable of passing bend tests required by Section IX for procedure or performance qualification may be qualified by a Fillet Weld Test in accordance with QW-180. In addition, a minimum of two cross sections of the qualification test plate (assembly) shall be ground and etched with a suitable etchant and visually examined at 10× magnification. The weld metal and adjacent base material of the ground and etched cross sections shall be free of cracks.

U-1443 Blending of Repaired Areas

After repair, the surface shall be blended into the surrounding surface.

U-1444 Examination of Repair Welds

Each repair weld of materials for Category 3 items for Class 1 pumps shall be examined by the method that originally disclosed the defect. The finished surface shall be examined by either the magnetic particle or liquid penetrant method in

accordance with Section V. The acceptance standards shall be those specified in paras. U-1430(a) and U-1430(b). Repair welds of materials for the other categories shall be in accordance with the material specification.

U-1445 Heat Treatment After Repair

(a) Materials listed in Table U-1610-1 which are repaired by welding shall be heat treated in accordance with the requirements of NB-4600, NC-4600 and ND-4600 as applicable, or as allowed by (c) below.

(b) Materials listed in Table U-1610-1 which are repaired by welding shall be heat treated and tempered or aged after repair, except as allowed by (c) below. The minimum tempering or aging temperature shall be as specified in Table U-1610-1 for the finished item.

(c) Repair weld procedures for welds not exceeding the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness shall be qualified by test weld specimens meeting the tensile and bend test requirements of Section IX, without PWHT, for the material repaired.

U-1446 Repair Weld Report

A record shall be made of each defect repair of Category 3 items for Class 1 pumps in which the depth of the repair cavity exceeds the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness. The record shall include the location and size of the repaired cavity, the welding material, the welding procedure, the heat treatment, and the examination results.

U-1450 WELDING REQUIREMENTS

Except as permitted in paras. U-1442 and U-1451, all welds shall be made using qualified welding procedures and welders or welding operators in accordance with Section IX.

U-1451 Special Fabrication Welds

Fillet welds and partial penetration welds $\frac{1}{4}$ in. (6 mm) and less in size may be made in the fabrication of pump items or between pump items where either of the items is a material listed in Table U-1610-1 provided welding is not prohibited by Note 2 in Table U-1610-1, and the procedures and welders are qualified as follows:

(a) a test assembly shall be made for each combination of materials to be welded;

(b) the test assembly shall be a duplicate of the production weld joint or a groove butt weld $\frac{1}{4}$ in. (6 mm) minimum thickness;

(c) the test assembly shall be sectioned (a minimum of four cross sections), ground, etched with a suitable etchant, and visually examined at $10\times$ magnification. All surfaces of the weld and adjacent base material(s) shall be free of cracks.

U-1452 Examination of Welds

All welds shall be examined by the magnetic particle or liquid penetrant method in accordance with Section V. The time of examination shall be in accordance

Page 480

with NB-5120, NC-5120 and ND-5120. Acceptance standards shall be as follows.

U-1453 Acceptance Standards

(a) Only indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant.

(b) The following relevant indications are unacceptable:

(1) any cracks or linear indications;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimensions of this area not to exceed 6 in. (152 mm), with the area taken in the most unfavorable location relative to the indications being evaluated.

U-1454 Heat Treatment of Welds

(a) Postweld heat treatment of welds which join materials listed in Table U-1610-1 shall be in accordance with the postweld heat treatment requirements of NB-4620, NC-4620 or ND-4620, as applicable.

(b) Postweld heat treatment of welds which join materials listed in Table U-1610-1 shall be in accordance with the postweld heat treatment requirements of NB-4620, NC-4620, or ND-4620, as applicable. Special techniques, such as local postweld heat treatment, may be necessary to avoid changing the base material properties of the item in location not adjacent to the weld. A change in the specified postweld heat treatment temperature will require requalification of the WPS in accordance with Section IX, para. QW-407.1.

(c) Postweld heat treatment of welds which join materials listed in Table U-1610-1 to materials listed in Section II, Part D, Table 1A shall be in accordance with the postweld heat treatment requirements of NB-4620, NC-4620 or ND-4620, as applicable. Special techniques, such as local postweld heat treatment, may be necessary to avoid changing the base material properties of the item in location not adjacent to the weld. A change in the specified postweld heat treatment temperature will require requalification of the WPS in accordance with Section IX, para. QW-407.1.

(d) Postweld heat treatment of welds for joining materials listed in Table U-1610-1 shall be in accordance with the heat treatment specified for the material of the finished item, i.e., the heat treatment required to obtain the tensile strength and/or yield strength listed in Table U-1610-1.

(e) Materials listed in Table U-1610-1 subject to material specification heat treatment after repair welding shall be welded to a procedure which shall demonstrate that the required strength can be met in the weld without affecting the properties of the base material.

(f) For fillet welds and partial penetration welds $\frac{1}{4}$ in. (6 mm) and less in size, postweld heat treatment is neither required nor prohibited, provided the requirements of para. U-1451 are met.

Page 481

Page 482

**TABLE U-1600-1
SUMMARY OF REQUIREMENTS**

Typical Items	Category No. & Pump Class	Stress Report	Certified Material Test Report	Non-destructive Examination	Impact Testing	Material Identif.
Pressure Retaining Items	Category 1 Class (All)	Subsection NB, NC, ND				
Pressure Retaining Bolting	Category 2 Class (All)	Subsection NB, NC, ND

- (1) Quality control system.
(2) Materials Manufacturer's Certificate of Compliance.
(3) Certified Material Test Reports required for impellers.
(4) When required for the pump per Design Specification.
(5) Ultrasonic Examination required for Class 1 shafting.
(6) Magnetic Particle or Liquid Penetrant Examination required for Class 1 impellers.
(7) Magnetic Particle or Liquid Penetrant Examination required for all Class 1, Category 3 items.

TABLE U-1600-1 SUMMARY OF REQUIREMENTS

Key to Fig. U-1500-1

Cat.	Pump Item	Name (Typical)
1	1-1	Casing
	1-2	Main Flange
	1-3	Heat Exchanger
	1-4	Seal Housing
	1-5	Thermal Barrier
	1-6	TB Connection Piping (Include Flange)
2	2-1	Main Flange Bolts
	2-2	Seal Housing Bolts
3	3-1	Shaft
	3-2	Impeller Nut
4	4-1	Impeller
	4-2	Diffuser
5	4-3	Bearing Support
	5-1	Diffuser Adapter (Casing Wear Ring)
6	5-2	Thermal Sleeve
	5-3	Radial Bearing Bolts
	5-4	Turning Vane/Thermal Barrier Bolts
	5-5	Diffuser/Diffuser Adapter Bolts
	5-6	Impeller Nut Locking Bolt
	5-7	Seals—Mechanical Seal (Metallic)
	5-8	Bearings/Journals and Shaft Sleeves
	6-1	Flange Gaskets
	6-2	Seal Housing O-Ring
	6-3	Radial Bearing
	6-4	Mechanical Seal (Nonmetallic)

NOTES:

- (1) Not to be used with Category 3 items, except for pumps with inlet piping connections 2 in. nominal pipe size and less.
- (2) Welding of these materials is not permitted.
- (3) Where the tensile strength, yield strength, tempering temperature, or aging temperature listed in Table U-1610-1 differ from the requirements of the material specification, the minimum requirements listed in Table U-1610-1 shall apply. The material shall be identified with this Appendix number in addition to the requirements for identification of para. U-1316.
- (4) Cross-bracketing indicates that any of the bracketed materials may be used with any of the bracketed properties.
- (5) The maximum tensile strength shall not exceed the minimum specified tensile strength listed in this Table by more than 40,000 psi.
- (6) Welding of this material is permitted provided the carbon content is 0.25% or less.
- (7) Service temperatures shall not exceed temperatures of 100°F below the aging or tempering temperature.
- (8) Material shall conform to Edition specified by N-Certificate Holder.

APPENDIX V INTERRUPTION OF CODE WORK

Page 493

Page 495

[98]

ARTICLE V-1000 INTERRUPTION OF CODE WORK

[98]

V-1100INTRODUCTION

[98]

V-1110 Scope

The scope of this Appendix is confined to those situations where the Code activities of a Certificate Holder are interrupted prior to completion of all Code assigned responsibilities. When this occurs, all completed in-process work must be clearly documented to ensure remaining activities and Code responsibilities are readily identifiable.

[98]

[98]

V-1200DEFINITIONS

(a) *Interruption of Code Activities:* The cessation of Code work by a Certificate Holder prior to completion of all assigned Code responsibilities. The cessation may result from project suspension or transfer of Code responsibilities from one Certificate Holder to another Certificate Holder.

(b) *Completed In-Process Work:* A Code activity on an item, part, subassembly, appurtenance, component, or support which has been accepted by the ANI for the Certificate Holder that performed the Code activity, but which requires additional work before the item, part, subassembly, appurtenance, component, or support can be stamped with the applicable Code symbol. Examples of completed in-process work include design activities, an individual weld or a weld pass, heat treatment of weld joints, and examination of welds or items after heat treatment.

[98]

[98]

V-1300DOCUMENTATION

(a) A memorandum of understanding shall be approved by the parties involved which documents the status of Code activities and acceptance of transfer responsibilities, where applicable. The memorandum shall be approved by the existing Certificate Holder and its ANI, the Certificate Holder which will provide continuity of responsibility and its ANI, where applicable. When the work is being performed at a nuclear power plant site, the memorandum shall also be approved by the Owner and the jurisdictional enforcement authority having jurisdiction at the nuclear power plant site.

(b) The memorandum of understanding shall reference Code Data Reports for completed work. For completed in-process work, Code Data Reports may also be used to document the status of Code activities. Additionally, the status of completed in-process work may also be indicated on drawings, diagrams, or other means and referenced in the memorandum.

[98]

[98]

V-1400 OTHER CONSIDERATIONS

(a) If a quality program such as that used by a Certificate Holder is utilized during the period of interruption, a review of completed work will not be required by the Certificate Holder assuming responsibility for completion of Code activities. The Certificate Holder assuming responsibility or its Authorized Nuclear Inspector may require evidence that an acceptable quality program has been in place.

(b) Once completed work or completed in-process work is accepted by an ANI, it meets Code requirements and need not be scrutinized by another Certificate Holder or ANI.

(c) To meet Code requirements, completed work shall be documented on the applicable Code Data Report and stamped as applicable.

(d) Completion of the applicable Code Data Report and application of the Code symbol stamp, where applicable, expressly signifies the Code status of completed work and completed in-process work.

[98]

[98]

V-1500 RESUMPTION OF CODE ACTIVITIES

Resumption of Code activities may be undertaken at any time by updating the original memorandum of understanding documenting the status of Code activities. The updated memorandum shall be approved by any new parties involved such as the Certificate Holder assuming responsibility for completion of Code activities, the Certificate Holder's ASME Accredited Authorized Nuclear Inspection Agency, and the organization contracting for the completion of Code activities. For Code activities to be performed at a nuclear plant site, the Owner and jurisdictional and enforcement authority shall also approve the updated memorandum of understanding.

**IMPORTANT INFORMATION ON THE 1998 BOILER AND PRESSURE VESSEL CODE
ADDENDA DISTRIBUTION SCHEDULE**

There is a change in the way the Addenda to the 1998 Edition of the ASME Boiler and Pressure Vessel Code are distributed. The 1998 Edition, published July 1, 1998, incorporates the 1998 Addenda revisions, additions, or deletions. There will be no separate 1998 Addenda issued in a replacement page format. Two additional Addenda to the 1998 Edition, in the form of replacement pages, will be issued on July 1, 1999 and July 1, 2000.

The Summary of Changes published with the 1998 Edition lists and describes the revisions that are part of the 1998 Addenda. These changes are identified with a margin note, **98**, denoting the affected area.

The Addenda for 1999 and 2000 will also have a Summary of Changes and identifiers printed on the replacement pages. The revisions, additions, or deletions will be incorporated directly into the affected pages. It is advisable to retain the title sheets and all replaced pages for reference.

The effective dates for Code Editions and Addenda are described in the Foreword.

Date of Issue - July 1, 1998
(Includes all Addenda dated December 1997 and earlier)

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

The footnotes in this document are part of this American National Standard.

ADDENDA

Colored-sheet Addenda, which include additions and revisions to individual Sections of the Code, are published annually and will be sent automatically to purchasers of the applicable Sections up to the publication of the 2001 Code. The 1998 Code is available only in the loose-leaf format; accordingly, the Addenda will be issued in the loose-leaf, replacement-page format.

INTERPRETATIONS

ASME issues written replies to inquiries concerning interpretation of technical aspects of the Code. The Interpretations for each individual Section will be published separately and will be included as part of the update service to that Section. They will be issued semiannually (July and December) up to the publication of the 2001 Code. Interpretations of Section III, Divisions 1 and 2, will be included with the update service to Subsection NCA.

CODE CASES

The Boiler and Pressure Vessel Committee meets regularly to consider proposed additions and revisions to the Code and to formulate Cases to clarify the intent of existing requirements or provide, when the need is urgent, rules for materials or constructions not covered by existing Code rules. Those Cases which have been adopted will appear in the appropriate 1998 Code Cases book: (1) Boilers and Pressure Vessels and (2) Nuclear Components. Supplements will be sent automatically to the purchasers of the Code Cases books up to the publication of the 2001 Code.

Page v

FOREWORD

The American Society of Mechanical Engineers set up a committee in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. This committee is now called the Boiler and Pressure Vessel Committee.

The Committee's function is to establish rules of safety governing the design, fabrication, and inspection during construction of boilers and pressure vessels, and to interpret these rules when questions arise regarding their intent. In formulating the rules, the Committee considers the needs of users, manufacturers, and inspectors of pressure vessels. The objective of the rules is to afford reasonably certain protection of life and property and to provide a margin for deterioration in service so as to give a reasonably long, safe period of usefulness. Advancements in design and material and the evidence of experience have been recognized.

This Code contains mandatory requirements, specific prohibitions, and nonmandatory guidance for construction,¹ and inservice inspection and testing activities. The Code does not address all aspects of these activities and those aspects which are not specifically addressed should not be considered prohibited. The Code is not a handbook and cannot replace education, experience, and the use of engineering judgment. The phrase *engineering judgment* refers to technical judgments made by knowledgeable engineers experienced in the application of the Code. Engineering judgments must be consistent with Code philosophy and such judgments must never be used to overrule mandatory requirements or specific prohibitions of the Code.

¹ Construction, as used in this Foreword, is an all-inclusive term comprising materials, design, fabrication, examination, inspection, testing, certification, and pressure relief.

The Committee recognizes that tools and techniques used for design and analysis change as technology progresses and expects engineers to use good judgment in the application of these tools. The designer is responsible for complying with Code rules and demonstrating compliance with Code equations when such equations are mandatory. The Code neither requires nor prohibits the use of computers for the design or analysis of components constructed to the requirements of the Code. However, designers and engineers using computer programs for design or analysis are cautioned that they are responsible for all technical assumptions inherent in the programs they use and they are responsible for the application of these programs to their design.

The Code does not fully address tolerances. When dimensions, sizes, or other parameters are not specified with tolerances, the values of these parameters are considered nominal and allowable tolerances or local variances may be considered acceptable when based on engineering judgment and standard practice as determined by the engineer.

The Boiler and Pressure Vessel Committee deals with the care and inspection of boilers and pressure vessels in service only to the extent of providing suggested rules of good practice as an aid to owners and their inspectors.

The rules established by the Committee are not to be interpreted as approving, recommending, or endorsing any proprietary or specific design or as limiting in any way the manufacturer's freedom to choose any method of design or any form of construction that conforms to the Code rules.

The Boiler and Pressure Vessel Committee meets regularly to consider revisions of the rules, new rules as dictated by technological development, Code Cases, and requests for interpretations. Only the Boiler and Pressure Vessel Committee has the authority to provide official interpretations of this Code. Requests for revisions, new rules, Code Cases, or interpretations shall be addressed to the Secretary in writing and shall give full particulars in order to receive consideration and action (see Mandatory Appendix covering preparation of technical inquiries). Proposed revisions to the Code resulting from inquiries will be presented to the Main Committee for appropriate action. The action of the Main Committee becomes effective only after confirmation by letter ballot of the Committee and approval by ASME.

to invite comments from all interested persons. After the allotted time for public review and final approval by ASME, revisions are published annually in Addenda to the Code.

Code Cases may be used in the construction of components to be stamped with the ASME Code symbol beginning with the date of their approval by ASME.

Code Editions may be used on or after the date of issue shown in the Edition. After Code revisions are approved by ASME, they may be used beginning with the date of issue shown on the Addenda. Revisions to material specifications are originated by the American Society for Testing and Materials (ASTM) and other recognized national or international organizations, and are usually adopted by ASME. However, those revisions may or may not have any effect on the suitability of material, produced to earlier editions of specifications, for use in ASME construction. ASME material specifications approved for use in each construction Code are listed in the Appendices of Section II, Parts A and B. These Appendices list, for each specification, the latest edition adopted by ASME, and earlier and later editions considered by ASME to be identical for ASME construction.

Owners of nuclear power plants are cautioned that Code Editions, Addenda, and Cases to be used in construction shall be acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

Each state and municipality in the United States and each province in Canada that adopts or accepts one or more Sections of the Boiler and Pressure Vessel Code is invited to appoint a representative to act on the Conference Committee to the Boiler and Pressure Vessel Committee. Since the members of the Conference Committee are in active contact with the administration and enforcement of the rules, the requirements for inspection in this Code correspond with those in effect in their respective jurisdictions. The required qualifications for an Authorized Inspector under these rules may be obtained from the administrative authority of any state, municipality, or province which has adopted these rules.

The Boiler and Pressure Vessel Committee in the formulation of its rules and in the establishment of maximum design and operating pressures considers materials, construction, method of fabrication, inspection, and safety devices. Permission may be granted to regulatory bodies and organizations publishing safety standards to use a complete Section of the Code by reference. If usage of a Section, such as Section IX, involves exceptions, omissions, or changes in provisions, the intent of the Code might not be attained.

Where a state or other regulatory body, in the printing of any Section of the Boiler and Pressure Vessel Code, makes additions or omissions, it is recommended that such changes be clearly indicated.

The National Board of Boiler and Pressure Vessel Inspectors is composed of chief inspectors of states and municipalities in the United States and of provinces in Canada that have adopted the Boiler and Pressure Vessel Code. This Board, since its organization in 1919, has functioned to uniformly administer and enforce the rules of the Boiler and Pressure Vessel Code. The cooperation of that organization with the Boiler and Pressure Vessel Committee has been extremely helpful.

The Code Committee does not rule on whether a component shall or shall not be constructed to the provisions of the Code. The Scope of each Section has been established to identify the components and parameters considered by the Committee in formulating the Code rules. Laws or regulations issued by municipality, state, provincial, federal, or other enforcement or regulatory bodies having jurisdiction at the location of an installation establish the mandatory applicability of the Code rules, in whole or in part, within their jurisdiction. Those laws or regulations may require the use of this Code for vessels or components not considered to be within its Scope or may establish additions or deletions in that Scope. Accordingly, inquiries regarding such laws or regulations are to be directed to the issuing enforcement or regulatory body.

Questions or issues regarding compliance of a specific component with the Code rules are to be directed to the ASME Certificate Holder (Manufacturer). Inquiries concerning the interpretation of the Code are to be directed to the ASME Boiler and Pressure Vessel Committee. ASME is to be notified should questions arise concerning improper use of an ASME Code symbol.

The specifications for materials given in Section II are identical with or similar to those of specifications published by ASTM, AWS, and other recognized national or international organizations. When reference is made in an ASME material

specification to a non- ASME specification for which a companion ASME specification exists, the reference shall be interpreted as applying to the ASME material specification. Not all materials included in the material specifications in Section II have been adopted for use in this Section. Usage is limited to those materials and grades listed in at least one of the tables of Section II, Part D, Subpart 1, identified as applicable to this Section. All materials allowed by this Section and used for construction within the scope of these rules shall be furnished in accordance with material specifications

Page ix

contained in Section II or referenced in Appendices A of Section II, Parts A and B except where otherwise provided in Code Cases or in this Section of the Code. Materials covered by these specifications are acceptable for use in items covered by the Code Sections only to the degree indicated in the applicable Section. Materials for Code use should preferably be ordered, produced, and documented on this basis. Material produced to an acceptable specification with requirements different from the requirements of the corresponding specification listed in Appendix A of Part A or Part B may also be used in accordance with the above, provided the material manufacturer or vessel manufacturer certifies with evidence acceptable to the Authorized Inspector that the corresponding ASME specification requirements of specifications listed in Appendix A of Part A or Part B have been met. Material produced to an acceptable material specification is not limited as to country of origin.

When required by context in this Section, the singular shall be interpreted as the plural, and vice-versa; and the feminine, masculine, or neuter gender shall be treated as such other gender as appropriate.

Publication of the SI (Metric) Edition of the ASME Boiler and Pressure Vessel Code was discontinued with the 1986 Edition. Effective October 1, 1986, the SI Edition was withdrawn as an ASME Boiler and Pressure Vessel Code document.

Page xi

STATEMENT OF POLICY ON THE USE OF CODE SYMBOLS AND CODE AUTHORIZATION IN ADVERTISING

ASME has established procedures to authorize qualified organizations to perform various activities in accordance with the requirements of the ASME Boiler and Pressure Vessel Code. It is the aim of the Society to provide recognition of organizations so authorized. An organization holding authorization to perform various activities in accordance with the requirements of the Code may state this capability in its advertising literature.

Organizations that are authorized to use Code Symbols for marking items or constructions which have been constructed and inspected in compliance with the ASME Boiler and Pressure Vessel Code are issued Certificates of Authorization. It is the aim of the Society to maintain the standing of the Code Symbols for the benefit of the users, the enforcement jurisdictions, and the holders of the symbols who comply with all requirements.

Based on these objectives, the following policy has been established on the usage in advertising of facsimiles of the symbols, Certificates of Authorization, and reference to Code construction. The American Society of Mechanical Engineers does not "approve," "certify," "rate," or "endorse" any item, construction, or activity and there shall be no statements or implications which might so indicate. An organization holding a Code Symbol and/or a Certificate of Authorization may state in advertising literature that items, constructions, or activities "are built (produced or performed) or activities conducted in accordance with the requirements of the ASME Boiler and Pressure Vessel Code," or "meet the requirements of the ASME Boiler and Pressure Vessel Code."

The ASME Symbol shall be used only for stamping and nameplates as specifically provided in the Code. However, facsimiles may be used for the purpose of fostering the use of such construction. Such usage may be by an association or a society, or by a holder of a Code Symbol who may also use the facsimile in advertising to show that clearly specified items will carry the symbol. General usage is permitted only when all of a manufacturer's items are constructed under the rules.

The ASME logo, which is the cloverleaf with the letters ASME within, shall not be used by any organization other than ASME.

STATEMENT OF POLICY ON THE USE OF ASME MARKING TO IDENTIFY MANUFACTURED ITEMS

The ASME Boiler and Pressure Vessel Code provides rules for the construction of boilers, pressure vessels, and nuclear components. This includes requirements for materials, design, fabrication, examination, inspection, and stamping. Items constructed in accordance with all of the applicable rules of the Code are identified with the official Code Symbol Stamp

described in the governing Section of the Code.

Markings such as "ASME," "ASME Standard," or any other marking including "ASME" or the various Code Symbols shall not be used on any item which is not constructed in accordance with all of the applicable requirements of the Code.

Items shall not be described on ASME Data Report Forms nor on similar forms referring to ASME which tend to imply that all Code requirements have been met when, in fact, they have not been. Data Report Forms covering items not fully complying with ASME requirements should not refer to ASME or they should clearly identify all exceptions to the ASME requirements.

ORGANIZATION OF SECTION III

1. GENERAL

Section III consists of Division 1, Division 2, and Division 3. These Divisions are broken down into Subsections and are designated by capital letters preceded by the letter "N" for Division 1, by the letter "C" for Division 2, and by the letter "W" for Division 3. The following eleven books make up the three Divisions.

Subsection NCA - General Requirements for Division 1 and Division 2

Division 1

Subsection NB - Class 1 Components

Subsection NC - Class 2 Components

Subsection ND - Class 3 Components

Subsection NE - Class MC Components

Subsection NF - Supports

Subsection NG - Core Support Structures

Subsection NH - Class 1 Components in Elevated Temperature Service

Appendices

Division 2 - Code for Concrete Reactor Vessels and Containments

Division 3 - Containment Systems and Transport Packagings for Spent Nuclear Fuel and High Level Radioactive Waste

The Division 2 book includes Subsection CC - Concrete Containments and Division 2 Appendices.

The Division 3 book includes Subsections WA and WB for General Requirements and Class TP (Type B) Containment, respectively.

2. SUBSECTIONS

Subsections are divided into Articles, Subarticles, paragraphs, and, where necessary, subparagraphs and subsubparagraphs.

3. ARTICLES

Articles are designated by the applicable letters indicated above for the Subsections followed by Arabic numbers, such as NB-1000. Where possible, Articles dealing with the same topics are given the same number in each Subsection in accordance with the following general scheme:

Article Number	Title
1000	Introduction or Scope
2000	Material
3000	Design
4000	Fabrication and Installation
5000	Examination
6000	Testing
7000	Overpressure Protection
8000	Nameplates, Stamping, and Reports

The numbering of Articles and the material contained in the Articles may not, however, be consecutive. Due to the fact that the complete outline may cover phases not applicable to a particular Subsection or Article, the rules have been prepared with some gaps in the numbering.

4. SUBARTICLES

Subarticles are numbered in units of 100, such as NB-1100.

5. SUBSUBARTICLES

Subsubarticles are numbered in units of 10, such as NB-2130, and generally have no text. When a number such as NB-1110 is followed by text, it is considered a paragraph.

6. PARAGRAPHS

Paragraphs are numbered in units of 1, such as NB-2121.

7. SUBPARAGRAPHS

Subparagraphs, when they are *major* subdivisions of a paragraph, are designated by adding a decimal followed by one or more digits to the paragraph number, such as NB-1132.1. When they are *minor* subdivisions of a paragraph, subparagraphs may be designated by lowercase letters in parentheses, such as NB-2121(a).

8. SUBSUBPARAGRAPHS

Subsubparagraphs are designated by adding lowercase letters in parentheses to the *major* subparagraph numbers, such as NB-1132.1(a). When further subdivisions of *minor* subparagraphs are necessary, subsubparagraphs are designated by adding Arabic numerals in parentheses to the subparagraph designation, such as NB-2121(a)(1).

Page xxiv

9. REFERENCES

References used within Section III generally fall into one of the following four categories.

A. References to Other Portions of Section III

When a reference is made to another Article, Subarticle, or paragraph, all numbers subsidiary to that reference shall be included. For example, reference to NB-3000 includes all material in Article NB-3000; reference to NB-3200 includes all material in Subarticle NB-3200; reference to NB-3230 includes all paragraphs NB-3231 through NB-3236.

B. References to Other Sections

Other Sections referred to in Section III are:

Section II, Materials. When a requirement for a material, or for the examination or testing of a material, is to be in accordance with a specification such as SA-105, SA-370, or SB-160, the reference is to material specifications in Section II. These references begin with the letter "S."

Section V, Nondestructive Examination. Section V references begin with the letter "T" and relate to the nondestructive examination of material or welds.

Section IX Welding and Brazing Qualifications. Section IX references begin with the letter "Q" and relate to welding and brazing requirements.

Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components. When a reference is made to inservice inspection, the rules of Section XI shall apply.

C. Reference to Specifications and Standards Other Than Published in Code Sections

(1) Specifications for examination methods and acceptance standards to be used in connection with them are published by the American Society for Testing and Materials. At the time of publication of Section III, some such specifications were not included in Section II of this Code. A reference to ASTM E 71-64 refers to the specification so designated by and published by ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

² The American National Standards Institute (ANSI) was formerly known as the American Standards Association. Standards approved by the Association were designated by the prefix "ASA" followed by the number of the standard and the year of publication. More recently, the American National Standards Institute was known as the United States of American Standards Institute. Standards were designated by the prefix "ASAS" followed by the number of the standard and the year of publication. While the letters of the prefix have changed with the name of the organization, the numbers of the standards have remained unchanged.

(2) Dimensional standards covering products such as valves, flanges, and fittings are sponsored and published by the American Society of Mechanical Engineers and approved by the American National Standards Institute.² When a product is to conform to such a standard, for example ANSI B16.5, the standard is approved by the American National Standards Institute. The applicable year of issue is that suffixed to its numerical designation in Table NB-3132-1, for example ANSI B16.5-1977. Standards published by the American Society of Mechanical Engineers are available from ASME, 22 Law Drive, Box 2300, Fairfield, NJ 07007-2300.

(3) Dimensional and other types of standards covering products such as valves, flanges, and fittings are also published by the Manufacturers Standardization Society of the Valve and Fittings Industry and are known as Standard Practices. When a product is required by these rules to conform to a Standard Practice, for example MSS SP-6, the Standard Practice referred to is published by the Manufacturers Standardization Society of the Valve and Fittings Industry, 127 Park Street, N.E., Vienna, VA 22180. The applicable year of issue of such a Standard Practice is that suffixed to its numerical designation in Table NB-3132-1, for example MSS SP-6-1963.

(4) Specifications for welding and brazing materials are published by the American Welding Society, 550 N.W. LeJeune Road, Miami, FL 33135. Specifications of this type are incorporated in Section II and are identified by the AWS designation with the prefix "SF," for example SFA-5.1.

(5) Standards applicable to the design and construction of tanks and flanges are published by the American Petroleum Institute and have designations such as API-620 and API-2000. When documents so designated are referred to in Section III, they are standards published by the American Petroleum Institute.

D. References to Appendices

Two types of Appendices are used in Section III and are designated Mandatory and Nonmandatory.

(1) Mandatory Appendices contain requirements which must be followed in construction; such references are designated by a Roman numeral followed by Arabic numerals. References to II-1100 or XI-3212, for example, relate to the Mandatory Appendices.

(2) Nonmandatory Appendices provide information or guidance for the use of Section III; such references are designated by a capital letter followed by Arabic numerals. A reference to D-1100, for example, relates to a Nonmandatory Appendix.

American Society Of Mechanical Engineers

SEC III D2 INTRO

INTRODUCTION TO SECTION III, DIVISION 2

Page xxv

This document has been prepared by the Joint ACI-ASME Technical Committee on Concrete Pressure Components for Nuclear Service under the sponsorship of the American Concrete Institute and the American Society of Mechanical Engineers. The two Societies have agreed that it will be published as Section III, Division 2, of the ASME Boiler and Pressure Vessel Code. Any changes to it shall be subject to the standardization procedures of the two sponsoring Societies.

The basic materials for this document were provided by two committee reports, one by ACI and the other by ASME. The ACI Committee 349, Criteria for Nuclear Containment Vessels, and the ASME Boiler and Pressure Vessel Code Committee, Section III, Division 2, Subgroup on Concrete Components, submitted their completed committee reports in September 1971 to ACI and ASME, respectively.

These two documents were melded into a single document dated January 17, 1972, and entitled *Proposed Standard - Code*

for Concrete Reactor Vessels and Containments. A second draft was published August 1, 1972, that included new and revised technical material plus administrative agreements reached by the two Societies. Finally, after approval was received from the two Societies, a third and final draft was published in April 1973 for public "trial use and comment" for a period of about one year. During that year numerous public comments and suggestions were received from different segments of industry and regulatory agencies. In addition, two public hearings were held on the Code: the first on October 10, 1973, in Ottawa, Canada, the second on November 28, 1973, in Atlanta, Georgia. The consideration of all comments received as of November 28, 1973, resulted in a series of six Committee Addenda which were incorporated in the Code. The results of these three years of effort by the Committee have culminated in the present document.

The Joint Committee, whose membership includes individuals from both ACI and ASME and many others actively involved in the field, was formed in September 1971. The three primary goals established for the Committee are:

- (a) to establish rules in the form of a code for the design, construction, inspection, and testing of composite concrete and steel components for reactor vessels and containments for nuclear power reactors;
- (b) to interpret these rules when questions arise regarding their intent;
- (c) to periodically update code provisions, making full use of the expedited procedure for revision of standards as necessary.

It is expected that comments and discussions will continue to be received by the Joint Committee for review. Comments shall state clearly which area and wording of the Code is being discussed. Suggested revisions shall be worded as parallel text, giving both the present wording and showing how the proposed changed paragraphs should read, and shall be accompanied by a commentary (including references where appropriate) to support the proposed recommendations. Discussions, commentaries, and committee actions will be printed in the publications of the two Societies. Discussions may be sent to either the ACI or ASME headquarters marked to the attention of the Joint ACI-ASME Committee.

Page xxvii

THE AMERICAN CONCRETE INSTITUTE

The American Concrete Institute was organized in 1905 to provide industry standards in the field of concrete usage. The organization, which was formed as a result of meetings begun during the Engineering Congress at the Louisiana Purchase Exposition in St. Louis in 1904, was initially entitled the National Association of Cement Users. In 1913, the name of the Society was changed to the American Concrete Institute to better fit the actual scope of its activities and aims, which are to further engineering education, scientific investigation, and scientific research by organizing the efforts of its members for a nonprofit, public service in gathering, correlating, and disseminating information for the improvement of the design, construction, manufacture, use, and maintenance of concrete products and structures.

The day-to-day operation of ACI is administered by an Executive Director, under general supervision of its 18-member Board of Direction, which assigns a part of its administrative duties to standing committees, the ACI Standards Board, and various technical committees.

ACI - TECHNICAL ACTIVITIES COMMITTEE

The Technical Activities Committee, which is appointed by the Board of Direction, is responsible for Institute technical publications, review of standards, the technical program at conventions, and continuing studies of technical committees, from which arise recommendations for the activities, and the formation or discharge of these groups. TAC members are selected by the ACI Board to represent ACI's varied interests.

ACI - STANDARDS BOARD

The Standards Board, also appointed by the Board of Direction, is responsible for matters of policy, procedure, and appeal pertaining to ACI Standards. All proposed new standards or revisions to existing standards, including minority reports from sponsoring technical committees, are forwarded to the Standards Board through the Technical Activities Committee. On release by the Standards Board, these are published, and after ratification by letter ballot of the ACI membership at large are then available for public use. The primary functions of the Standards Board are to verify that proper standardization procedures have been followed and to rule on matters of policy as related to standards.

ACI - TECHNICAL AND EDUCATIONAL COMMITTEES

Much of the important work of the American Concrete Institute is performed by technical committees that prepare committee

reports and standards. Technical committees, composed of volunteer personnel, develop ACI recommendations in their respective fields. Their work, subject to review and approval by the Board of Direction through the Technical Activities Committee and the Standards Board, forms the basis for Institute Standards.

Educational committees, also composed of volunteer personnel, develop seminars, workshops, curriculum guides, and student manuals to further ACI's involvement in education. Their work, subject to review and approval by the ACI Educational Activities Committee, forms the basis for Institute manuals and training programs.

American Society Of Mechanical Engineers

SEC III D2 CC-1000

ARTICLE CC-1000 INTRODUCTION

Page 1

SUBSECTION CC

CONCRETE CONTAINMENTS

(PRESTRESSED OR REINFORCED)

Page 3

CC-1100 SCOPE AND GENERAL REQUIREMENTS

CC-1110 SCOPE

Subsection CC establishes rules for material, design, fabrication, construction, examination, testing, marking, stamping, and preparation of reports for prestressed and reinforced concrete containments. The containments covered by this Subsection shall include the following:

- (a) structural concrete pressure resisting shells and shell components;
- (b) shell metallic liners;
- (c) penetration liners extending the containment liner through the surrounding shell concrete.

CC-1120 GENERAL REQUIREMENTS

The rules of Division 1 shall apply as required in this Subsection for parts and appurtenances not backed by structural concrete for load carrying purposes. Those parts or appurtenances stamped in accordance with Division 2 shall meet the requirements of Subsection NCA, CC-1000, CC-6000, CC-7000, and CC-8000 in lieu of the corresponding requirements of Division 1. Those parts or appurtenances stamped in accordance with Division 1 shall meet all the requirements of Division 1 and NCA-2134(e).

CC-1130 RULES FOR CONCRETE CONTAINMENTS

Containments having a Design Pressure greater than 5 psi (35 kPa) which are classified as Subsection CC containments shall be constructed in accordance with the rules of this Subsection.

CC-1140 BOUNDARIES OF JURISDICTION

(a) The jurisdiction of this Subsection for the containment shall conform to the requirements of NCA-3254.2 supplemented by the provisions below.

(b) When a structural concrete support is constructed as an integral part of the containment, it shall be included within the jurisdiction of these criteria.

July 1, 1998
American Society Of Mechanical Engineers
SEC III D2 CC-2000
ARTICLE CC-2000 MATERIAL

Page 7

CC-2100 GENERAL REQUIREMENTS FOR MATERIAL

CC-2110 SCOPE

CC-2111 Terms

- (a) The term *material* as used in this Subsection is defined in NCA-1220.
- (b) The terms *Metallic Material Manufacturer* and *Material Supplier* are defined in NCA-3800.
- (c) The terms *Nonmetallic Material Manufacturer* and *Constituent Supplier* are defined in NCA-3900.
- (d) The terms *pressure retaining* and *load bearing materials* apply to items such as concrete, reinforcing material, prestressing material, liners, attachments to liners and embedment anchors.
- (e) The requirements of this Article make reference to the term *thickness*. For the purpose intended, the following definitions of nominal thickness apply:
 - (1) *plate* - the thickness is the dimension of the short transverse direction
 - (2) *forgings* - the thickness is the dimension defined as follows:
 - (a) *hollow forgings* - the nominal thickness is measured between the inside and outside surfaces (radial thickness)
 - (b) *disk forgings* (axial length less than the outside diameter) - the nominal thickness is the axial length
 - (c) *flat ring forgings* (axial length less than the radial thickness) - for axial length ≤ 2 in. (51 mm), the axial length is the nominal thickness; for axial length > 2 in. (51 mm), the radial thickness is the nominal thickness
 - (d) *rectangular solid forgings* - the least rectangular dimension is the nominal thickness
 - (3) *castings* - the thickness shall be as defined in SA-613

CC-2112 Special Rules

Metallic material for parts and appurtenances which are not backed by concrete for load carrying purposes shall meet the requirements of Division 1. Material for attachments to parts meeting the requirements of Division 1 shall meet the requirements of this Article.

CC-2120 PRESSURE RETAINING AND LOAD BEARING MATERIAL

CC-2121 Permitted Material Specifications

- (a) Concrete constituents and concrete shall conform to the requirements of CC-2200. Metallic material for pressure retaining and load bearing purposes shall conform to the requirements of one of the specifications included in this Article or in Table I-1.2, Table I-2.2, and Table I-2.3 of Appendix I, and to all the special requirements of this Article which apply to the product form in which the material is used.
- (b) Metallic or nonmetallic material and constituents other than those described in (a) above shall not be used until the requirements of Appendix IV have been met.

(c) The requirements of this Article only apply to items associated with the pressure retaining or load bearing function of a component. Other construction equipment or apparatus such as forms, tie wires, chairs, supports, form ties, grease and grout fittings, retaining caps, seals, packing, and gaskets are not covered by this Article.

(d) Welding and brazing materials used in the manufacture of items shall comply with an SFA specification, except as otherwise permitted in Section IX, and shall also comply with the applicable requirements of this Article.

CC-2122 Special Requirements

CC-2122.1 Metallic Materials.

The special requirements stipulated in this Article shall apply in lieu of the requirements of the material specifications wherever these special requirements conflict with the material specification requirements. Where the special requirements include an examination, test, or treatment which is also required by the material specification, the examination, test, or treatment need be performed only once. All required examinations, tests, and treatments shall be performed as specified for each metallic product in this Article and may be performed by either the Metallic Material Manufacturer, Fabricator, or Constructor, as provided in CC-4121.

CC-2122.2 Nonmetallic Materials and Constituents.

All required examinations, tests, and treatments shall be performed as specified in this Article and

Page 12

may be performed by either the organization providing concrete constituents, the Nonmetallic Material Manufacturer, or the applicable Fabricator or Constructor, as provided in CC-4121.

CC-2122.3 Authorized Inspector.

Reports of all required examinations, tests, and treatments shall be made available to the Authorized Inspector of the applicable Fabricator or Constructor and provisions made for inspections as required by the Authorized Inspector.

CC-2123 Size Ranges of Metallic Material

Metallic material outside the limits of size or thickness given in any specification allowed by this Division may be used if the material is in compliance with the other requirements of the specification and no size limitation is given in the rules for construction. In those specifications in which chemical composition and mechanical properties are indicated to vary with size or thickness, any material outside the specification range shall be required to conform to the composition and mechanical properties shown for the nearest specified range.

CC-2130 CERTIFICATION OF MATERIAL

CC-2131 Introduction

A Certified Material Test Report (CMTR) or a Certificate of Compliance shall be provided for all metallic materials, nonmetallic materials, and concrete constituents in accordance with the following subparagraphs.

CC-2131.1 Certified Material Test Reports.

Certified Material Test Reports (CMTR) shall be provided for concrete constituents, plastic concrete, reinforcing system material, prestressing system material, liner material, other load bearing and pressure retaining material, and welding and brazing material, and shall include the following:

(a) certified reports of the actual results of all required chemical analyses, physical tests, mechanical tests, examinations (including radiographic film), repairs, and heat treatments (including times and temperatures) performed on the material;

(b) a statement listing any chemical analyses, tests, examinations, and heat treatment required by the material specification, which were not performed;

(c) a statement giving the manner in which the material is identified, including specific marking;

(d) the Manufacturer of plastic concrete shall provide a Certified Material Test Report consisting of a batch ticket with each individual batch of concrete. The information on the batch ticket shall include the weight or volume of constituents as provided in CC-4222.2.

CC-2131.2 Certificate of Compliance.

A Material Manufacturer's Certificate of Compliance with the material specification, grade, class, and heat treatment condition, as applicable, may be provided in lieu of a Certified Material Test Report for metallic material $\frac{3}{4}$ in. nominal pipe size and less (pipe, tube, flanges, and fittings), and bolting 1 in. nominal diameter and less. The Certificate of Compliance shall contain a description of the marking of the material.

CC-2131.3 Concrete Constituents

CC-2131.3.1 Laboratory Accreditation.

The tests required by CC-2200 shall be performed by an accredited laboratory that complies with ASTM C 1077, Standard Practice for Testing Concrete and Concrete Aggregates for Use in Construction and Criteria for Laboratory Evaluation.¹

CC-2131.3.2 Certified Material Test Reports.

The Certified Material Test Reports (CMTR) for concrete constituents shall meet the following requirements.

(a) The CMTR for aggregate shall certify that the aggregates are from the same source (natural deposit) as the aggregate qualified in accordance with CC-2222.

(b) The CMTR for cement shall include the standard chemical and physical test results in accordance with ASTM C 150, Specification for Portland Cement, or ASTM C 595, Specification for Blended Hydraulic Cement, and any optional requirements in the Construction Specification. Sampling and testing frequencies shall meet the requirements of ASTM C 183, Sampling Hydraulic Cement.

(c) The CMTR for air-entraining admixtures shall include infrared spectrophotometry traces, percent solids, percent chlorides, and pH of each manufacturing lot. A statement shall be included to certify that these tests or other included tests have established equivalence with admixtures tested in accordance with ASTM C 260, Air-Entraining Admixtures for Concrete.

(d) The CMTR for fly ash and pozzolans shall include the standard chemical and physical test results in accordance with ASTM C 618, Fly Ash and Raw or Calcined Natural Pozzolans for Use in Portland Cement Concrete, and any requirements in the Construction Specification.

¹ Such laboratory inspections can be provided by the Cement and Concrete Reference Laboratory (CCRL) of the National Institute of Standards and Technology, with accreditation programs provided by the National Voluntary Laboratory Accreditation Program (NVLAP), American Association for Laboratory Accreditation (AALA), and American Materials Engineering Council (CEMC).

Sampling and testing frequencies shall meet the requirements of ASTM C 311, Sampling and Testing Fly Ash for Use as an Admixture in Portland Cement Concrete.

(e) The CMTR for chemical admixtures shall include infrared spectrophotometry traces, percent solids, and percent chlorides of each manufacturing lot. A statement shall be included to certify that these tests or other included tests have established equivalence with admixtures tested in accordance with ASTM C 494, Chemical Admixtures for Concrete, or ASTM C 1017, Chemical Admixtures for Use in Producing Flowing Concrete.

(f) A CMTR for water and ice is not required.

CC-2131.4 Personnel Qualification.

Laboratory testing personnel performing tests required by CC-2000 may be qualified using appropriate industry or laboratory standards. The qualification and certification rules of Appendix VII are not mandatory for personnel performing tests required in CC-2200.

CC-2132 Certification by Fabricator or Constructor

The Fabricator or Constructor shall provide a Certified Material Test Report for all operations performed by him or his subcontractors. The Fabricator or Constructor shall certify that the contents of his report are correct and accurate and that all operations performed by him or his subcontractors are in compliance with the requirements of the material specification and this Subsection. Alternatively, the Fabricator or Constructor shall provide a Certified Material Test Report for those operations he performed and a Certified Material Test Report from each of his subcontractors for operations they performed. Material identification, including any marking code, shall be described in the Certified Material Test Report.

CC-2140 DETERIORATION OF MATERIAL AND COATINGS DURING SERVICE

Consideration of deterioration of material caused by service is outside the scope of this Subsection. It is the responsibility of the Owner to select material suitable for the conditions stated in the Design Specifications (NCA-3250), with specific attention being given to the effects of service conditions upon the properties of the material.

CC-2150 HEAT TREATMENT TO ENHANCE MECHANICAL PROPERTIES OF METALLIC MATERIAL

CC-2151 Carbon and Low Alloy Steels

Carbon and low alloy steels may be heat treated by quenching and tempering to enhance notch toughness. Postweld heat treatment of the material at a temperature of not less than 1100°F (593°C) may be considered to be the tempering phase of the heat treatment when postweld heat treatment is a requirement of CC-4500.

CC-2152 Procedures for Heat Treatment of Material

When heat treating temperature or time is required by the material specification and the rules of the Subsection, the heat treating shall be performed in temperature-surveyed and -calibrated furnaces or shall be performed with thermocouples in contact with the material or attached to blocks in contact with the material. Heat treating shall be performed under furnace loading conditions such that the heat treatment is in accordance with the material specification and the rules of this Subsection.

CC-2153 Steels for Prestressing

Wire, strand, or bars for prestressing systems may be heat treated, as in stress relieving, under load to enhance stress relaxation properties. Quenching and tempering treatments to produce specific mechanical properties are not permitted.

CC-2160 DIMENSIONAL STANDARDS

Dimensions of standard items for pipe, tube, fittings, valves, flanges, and gaskets shall comply with the standards and specifications listed in Table CC-2160-1, unless otherwise specified in the Construction Specification or designated in the Design Drawings.

CC-2200 CONCRETE AND CONCRETE CONSTITUENTS

CC-2210 INTRODUCTION

This Subarticle establishes qualification requirements for concrete constituents and plastic concrete. Testing to establish conformance to the requirements shall be performed prior to use. The required tests in CC-2200 may be performed by the organizations providing

concrete constituents, the Nonmetallic Material Manufacturer, or applicable Fabricator or Constructor. The quality control tests described in CC-5200 shall be performed by the Nonmetallic Material Manufacturer, or applicable Fabricator or Constructor.

**TABLE CC-2160-1
DIMENSIONAL STANDARDS¹**

Standard	Designation
Pipes and Tubes	
Welded and Seamless Wrought Steel Pipe	ASME B36.10m
Stainless Steel Pipe	ASME B36.19m
Fittings, Flanges, and Gaskets	
Pipe Flanges and Flanged Fittings	ASME B16.5
Factory Made Wrought Steel Butt welding Fittings	ASME B16.9 [Note (2)]
Forged Steel Fittings, Socket-Welding and Threaded	ASME B16.11
Ring-Joint Gaskets and Grooves for Steel Pipe Flanges	ASME B16.20
Nonmetallic Flat Gaskets for Pipe Flanges	ASME B16.21
Butt welding Ends	ASME B16.25
Wrought Steel Butt welding Short Radius Elbows and Returns	ASME B16.28
Stainless Steel Butt welding Fittings	MSS SP-43
Steel Pipeline Flanges	MSS SP-44
Factory Made Butt welding Fittings for Class 1 Nuclear Piping Applications	MSS SP-87
Large Diameter Carbon Steel Flanges	API 605
Standard for Steel Pipe Flanges for Waterworks Services	AWWA C207
Bolting	
Square and Hex Bolts and Screws (Inch Series), Including Hex Cap Screws, and Lag Screws	ASME B18.2.1
Square and Hex Nuts (Inch Series)	ASME B18.2.2
Socket Cap, Shoulder, and Set Screws (Inch Series)	ASME B18.3
Threads	
Unified Inch Screw Threads (UN and UNR Thread Form)	ASME B1.1a
Pipe Threads — General Purpose (Inch)	ASME B1.20.1
Gaging for Dryseal Pipe Threads (Inch)	ASME B1.20.5
Valves	
Valves — Flanged, Threaded, and Welded End	ASME B16.34

NOTES:

- (1) Standards incorporated in this Division by reference. The names of the sponsoring organizations are shown in the Reference Materials portion of this Division.
- (2) Analysis in accordance with ASME B16.9, paragraph 2.2, is acceptable only for caps and reducers.

TABLE CC-2160-1 DIMENSIONAL STANDARDS¹

CC-2211 General Requirements

- (a) Consideration shall be given to minimizing the temperature rise in concrete due to heat of hydration, and to proper strength development with respect to formwork removal, construction stresses, and application of prestress.
- (b) The concrete and its constituents shall be sufficiently investigated prior to use to ensure acceptable creep and other properties under the environmental conditions and the long-term requirements described in the Construction Specification.
- (c) The water-cement ratio is the ratio of the weight of water to the weight of cement. Where mineral admixture is used, the weight of mineral admixture shall be added to the weight of cement to determine the water-cement ratio.

CC-2212 Substitutions

When an alternate constituent must be substituted for a previously qualified constituent as an alternative to a complete requalification in accordance with CC-2200, the following requirements apply.

(a) The alternate concrete constituent shall meet the requirements of qualification tests required by CC-2220.

Page 15

(b) Prior to use, the Designer shall confirm the similarity and compatibility of the alternate constituent with the other previously qualified constituents.

(c) Prior to use, the Designer shall establish the need for and extent of testing required by CC-2230.

CC-2220 CONCRETE CONSTITUENTS

CC-2221 Cement

CC-2221.1 Material Requirements.

Cement shall conform to the requirements of ASTM C 150, Specification for Portland Cement, Type I, Type II, Type IV, Type V, or ASTM C 595, Specification for Blended Hydraulic Cements, Type IP, Type IP (MS) or Type IP (MH).

CC-2222 Aggregates

CC-2222.1 General.

Aggregates shall conform to the requirements of ASTM C 33, Specification for Concrete Aggregates, with the following additional requirements.

(a) Gradation may be adjusted in the Construction Specification provided the requirements of CC-2231.1 are met. Coarse aggregate gradations must require at least two separate gradation sizes if aggregate larger than 1 in. is specified.

(b) Coarse and fine aggregate for normal weight concrete, placed by the preplaced aggregate method, shall meet the gradation requirements specified in ACI 304, Recommended Practice for Measuring, Mixing, Transporting, and Placing Concrete.

(c) Coarse aggregate shall be rounded or cubical and shall contain less than 15% (by weight) flat and elongated particles as determined by CRD-C 119, Method of Test for Flat and Elongated Particles in Coarse Aggregate.

NOTE: A *flat particle* is defined as one having a ratio of width to thickness greater than three; an *elongated particle* is defined as one having a ratio of length to width greater than three.

(d) A petrographic examination in accordance with ASTM C 295, Recommended Practice for Petrographic Examination of Aggregates for Concrete, shall be performed.

(e) Based upon the petrographic examination results, additional tests may be required using ASTM C 227, Potential Alkali Reactivity of Cement-Aggregate Combinations (Mortar-Bar Method); ASTM C 289, Potential Reactivity of Aggregates (Chemical Method); ASTM C 342, Potential Volume Change of Cement-Aggregate Combinations; or ASTM C 586, Potential Alkali Reactivity of Carbonate Rocks for Concrete Aggregate (Rock Cylinder Method), as applicable.

(f) The water soluble chloride content of the aggregate shall be established by the methods described in ASTM D 1411, Water Soluble Chlorides Present as Admixes in Graded Aggregate Road Mixes.

(g) For reinforced concrete containment designed in accordance with CC-3521.1.1, the maximum loss of weight of the coarse aggregate, when tested in accordance with ASTM C 131, Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine, shall not exceed 40%.

(h) The maximum size of coarse aggregate shall not be larger than one-fifth of the narrowest dimension of the finished wall or slab, nor larger than three-fourths of the minimum clear spacing between individual reinforcing bars or wires, bundles of bars, or prestressing ducts, or embedments.

CC-2222.2 Heavy Weight Aggregates.

Heavy aggregates required for concrete denser than 160 lb/cu ft shall conform to one of the following:

(a) ASTM C 637, Specification for Aggregates for Radiation Shielding Concrete; or

(b) requirements as provided in the Construction Specification for steel punchings, sheared reinforcing steel, iron shot, or materials containing boron used as concrete aggregate.

CC-2223 Mixing Water

CC-2223.1 General Requirements.

Water for mixing and for manufacturing ice shall be clean, with a total solids content of not more than 2000 ppm as measured in accordance with ASTM D 1888 tests for particulate and dissolved matter in water. The mixing water and ice shall be tested for chlorides (Cl⁻) as determined by ASTM D 512, Chloride Ion in Industrial Water and Industrial Waste Water.

CC-2223.2 Additional Requirements.

A comparison of the proposed mixing water properties shall be made with distilled water by determining compressive strength in accordance with ASTM C 109, Compressive Strength of Hydraulic Cement Mortars (Using 2 in. or 50 mm Cube Specimens). The results obtained for the proposed mixing water shall not be lower by more than 10% of those obtained for distilled water.

CC-2224 Admixtures

CC-2224.1 General Requirements for Admixtures.

When admixtures are to be used, the Construction Specification shall specify the type, quantity, and any

Page 16

additional limitations. Admixtures containing more than 1%, by weight, of chloride ions shall not be used for prestressed containments.

CC-2224.2 Air-Entraining Admixtures.

Air-entraining admixtures shall conform to the requirements of ASTM C 260, Air-Entraining Admixtures for Concrete.

CC-2224.3 Chemical Admixtures.

Chemical admixtures shall conform to the requirements of ASTM C 494, Chemical Admixtures for Concrete.

CC-2224.4 Mineral Admixtures.

When mineral admixtures (fly ash and pozzolan) are used, the Construction Specification shall specify the type, source, and any additional limitations, such as a maximum permitted amount of available alkalis and/or chloride ions.

Fly ash and pozzolanic admixtures shall conform to the requirements of ASTM C 618, Fly Ash and Raw or Calcined Natural Pozzolans for Use in Portland Cement Concrete.

CC-2224.5 Special Grouting Admixtures, Including Grout Fluidifier.

When special grouting admixtures, including grout fluidifier, are used, the Construction Specification shall specify the type and any additional limitations, such as a maximum permitted amount of available alkalis and/or chloride ions. In the preparation of cement grout, other types of admixtures, including those containing gels or gelling agents for the purpose of controlling loss of water from the grout, may be used, if permitted in the Construction Specification.

CC-2224.6 Grout Fluidifier.

Grout fluidifier for use with preplaced aggregate concrete shall conform to the requirements of ASTM C 937, Grout Fluidifier for Preplaced Aggregate Concrete.

CC-2224.7 Chemical Admixtures for Use in Producing Flowing Concrete.

Chemical admixtures for use in producing flowing concrete shall conform to the requirements of ASTM C 1017, Chemical Admixtures for Use in Producing Flowing Concrete.

CC-2230 CONCRETE MIX DESIGN

CC-2231 Concrete Properties

CC-2231.1 General Requirements.

The properties of concrete which influence the design of the containment shall be established in the Construction Specification. Concrete mixes will normally be established on the basis of strength, workability limits, and heat rise.

**TABLE CC-2231-1
CONCRETE PROPERTIES**

Property	Test Method
Slump	ASTM C 143
Compressive strength	ASTM C 39
Flexural strength	ASTM C 78
Splitting tensile strength	ASTM C 496
Static modulus of elasticity	ASTM C 469
Poisson's ratio	ASTM C 469
Coefficient of thermal conductivity	CRD-C 44
Coefficient of thermal expansion	CRD-C 39
Creep of concrete in compression	ASTM C 512
Shrinkage coefficient (length change of cement-mortar and concrete)	ASTM C 157
Density (specific gravity)	ASTM C 642
Maximum temperature rise in concrete	CRD-C 36

TABLE CC-2231-1 CONCRETE PROPERTIES

CC-2231.2 Chloride Content.

The water soluble chloride content of the concrete shall not exceed 0.15% by weight of portland cement for reinforced concrete containments and prestressed concrete containments where the prestressing tendons are placed in ducts and protected by cement grout or a permanent corrosion prevention coating in accordance with CC-2442.3.2. The water soluble chloride content of the concrete shall not exceed 0.06% by weight of portland cement for concrete that will be placed in direct contact with prestressing steel. The chloride content of the water and ice (CC-2223), aggregate (CC-2222), and liquid admixtures (CC-2224) shall be determined separately and combined to determine the total water soluble chloride content of the concrete.

CC-2231.3 Alkali Content.

If aggregate examination and testing [CC-2222.1(c) and (d)] indicates the presence of material known to be capable of participating in alkali-aggregate reaction, the Construction Specification shall establish an appropriate test program which will provide a rational basis to establish the suitability of each concrete constituent. Any additional limitation shall then be established in the Construction Specification.

CC-2231.4 Specified Properties

(a) The applicable concrete properties given in Table CC-2231-1 shall be defined in the Construction Specification. Testing shall be performed prior to construction with the exception of creep tests conforming to ASTM C 512, Standard Test Method for Creep of Concrete in Compression. Creep tests shall be completed prior to the start of prestressing. Testing required as a result

Page 17

of changes in concrete proportions or constituents shall be performed as soon as the change is initiated.

(b) The Construction Specification shall specify the age, strength, and temperature at which the applicable properties listed in Table CC-2231-1 shall be obtained and any environmental or design conditions which apply. If properties other than those listed in Table CC-2231-1 are required, they shall be defined in the Construction Specification.

CC-2231.5 Physical Properties

(a) Where the Construction Specification includes maximum allowable creep limits (rate and total), tests shall be performed at least for the limiting combination of stress-strength ratios, ages of loading, temperature levels, and cycles stated in the Construction Specification. The creep test procedure shall be based on ASTM C 512, Standard Test Method for Creep of Concrete in Compression, with modifications for specimen curing and sealing, and for testing temperatures as described in the Construction Specification.

(b) Where the Construction Specification defines an allowable range of secant moduli of elasticity, Poisson's ratios, and loading rates, concrete specimens shall be tested at those loading rates and the experimental values determined. The testing procedures and acceptance standards shall be based on ASTM C 469, Method of Test for Static Young's Modulus of Elasticity and Poisson's Ratio in Compression of Cylindrical Concrete Specimens, with suitable modifications.

CC-2231.6 Thermal Properties.

When required by the Construction Specification, the effect of thermal cycles on concrete properties shall be determined by the test standards described therein.

CC-2231.7 Durability

CC-2231.7.1 Concrete Subject to Freezing Temperatures.

Concrete that, after curing, will be subject to freezing temperatures while wet shall have an air content within the limits of Table CC-2231-2 and the water-cement ratio shall not exceed 0.50 by weight. For specified compressive strength f' of 5000 psi or greater, the air content indicated in Table CC-2231-2 may be reduced 1%.

CC-2231.7.2 Watertight Concrete.

Concrete that is intended to be watertight shall have a maximum water-cement ratio of 0.50 for exposure to fresh water and 0.45 for exposure to brackish or sea water.

CC-2231.7.3 Sulfate Resisting Concrete.

Concrete to be exposed to sulfate-containing solutions shall conform to the requirements of Table CC-2231.7.3-1.

**TABLE-CC-2231-2
CONCRETE AIR CONTENT FOR VARIOUS
SIZES OF COARSE AGGREGATES**

Nominal Maximum Size of Coarse Aggregate, in.	Total Air Content (volume), % [Notes (1), (2)]
$\frac{3}{8}$	6
$\frac{1}{2}$	5.5
$\frac{3}{4}$	5
1	4.5
$1\frac{1}{2}$	4.5
2	4
3	3.5

NOTES:

- (1) Air content shall not vary more than 1.5% from the listed value.
- (2) These air contents apply to total mix, as for the preceding aggregate sizes. When testing these contents, however, aggregate larger than $1\frac{1}{2}$ in. is removed by hand-picking or sieving and air content is determined on the minus $1\frac{1}{2}$ in. fraction of mix. (Tolerance on air content applies to this value.) Air content of total mix is computed from value determined on the minus $1\frac{1}{2}$ in. fraction.

TABLE CC-2231-2 CONCRETE AIR CONTENT FOR VARIOUS SIZES OF COARSE AGGREGATES

CC-2231.7.4 Corrosive Protection.

For protection of concrete exposed to brackish or sea water or frequent spray from these sources, the water-cement ratio shall not exceed 0.40 except that if the minimum concrete cover required by CC-3534.1 is increased by 0.5 in.

ratio shall not exceed 0.40 except that if the minimum concrete cover required by CC-3534.1 is increased by 0.5 in. (13 mm), the water-cement ratio may be increased to 0.45.

CC-2232 Selection of Concrete Proportions

CC-2232.1 Introduction.

Proportions of materials for concrete shall be established to provide:

- (a) workability and consistency to permit concrete to be worked readily into forms and around reinforcement under conditions of placement to be employed, without segregation or excessive bleeding;
- (b) resistance to special exposures as required by CC-2231.7;
- (c) conformance with the strength test requirements of CC-5232.3.

CC-2232.2 Different Materials.

Where different materials are to be used for different portions of proposed work, each combination shall be evaluated.

CC-2232.3 Basis of Selection.

Concrete proportions, including water-cement ratio, shall be established on the basis of field experience and/or trial mixtures with materials to be employed, except as required by CC-2231.7.

Page 18

**TABLE CC-2231.7.3-1
REQUIREMENTS FOR CONCRETE EXPOSED TO SULFATE-CONTAINING SOLUTIONS**

Sulfate Exposure	Water Soluble Sulfate (SO ₄) in Soil, Percent by Weight	Sulfate (SO ₄) in Water, ppm	Cement Type (CC-2221.1 and CC-2224.2.2)	Maximum Water-Cement Ratio, by Weight [Note (1)]
Negligible	0.00–0.10	0–150	...	...
Moderate [Note (2)]	0.10–0.20	150–1500	II, IP(MS), V	0.50
Severe	0.20–2.00	1500–10,000	V	0.45
Very Severe	Over 2.00	Over 10,000	V plus pozzolan [Note (3)]	0.45

NOTES:

- (1) A lower water-cement ratio or higher strength may be required for watertightness or for protection against corrosion of embedded items or freezing and thawing.
- (2) Seawater.
- (3) Pozzolan that has been determined by test or service record to improve sulfate resistance when used in concrete containing Type V cement.

TABLE CC-2231.7.3-1 REQUIREMENTS FOR CONCRETE EXPOSED TO SULFATE-CONTAINING SOLUTIONS

CC-2233 Proportioning on the Basis of Field Experience and/or Trial Mixtures

CC-2233.1 Standard Deviation.

Standard deviation shall be calculated using the methods of ACI 214, Recommended Practice for Evaluation of Strength Test Results of Concrete.

CC-2233.1.1 Test Record Requirements.

Where a concrete production facility has test records, a standard deviation shall be established. Test records from which a standard deviation is calculated shall:

(a) represent materials, quality control procedures, and conditions similar to those expected, and changes in materials and proportions within the test records shall not have been more restricted than those for proposed work;

(b) represent concrete produced to meet a specified strength or strengths f'_c within 1000 psi (6.9 MPa) of that specified for proposed work;

(c) consist of at least 30 consecutive tests or two groups of consecutive tests totaling at least 30 tests as defined in CC-5232.3.2(a), except as provided in CC-2233.1.2.

CC-2233.1.2 Alternative Test Record Requirements.

Where a concrete production facility does not have test records meeting the requirements of CC-2233.1.1, but does have a record based on 15 to 29 consecutive tests, a standard deviation may be established as the product of the calculated standard deviation and modification factor of Table CC-2233.1.2-1. To be acceptable, the test record must meet requirements (a) and (b) of CC-2233.1.1, and represent only a single record of consecutive tests that span a period of not less than 45 calendar days.

**TABLE CC-2233.1.2-1
MODIFICATION FACTOR FOR STANDARD DEVIATION
WHEN LESS THAN 30 TESTS ARE AVAILABLE**

Number of Tests ¹	Modification Factor for Standard Deviation ²
Less than 15	Use Table CC-2233.2.2-1
15	1.16
20	1.08
25	1.03
30 or more	1.00

NOTES:

(1) Interpolate for intermediate numbers of tests.

(2) Modified standard deviation to be used to determine required average strength f'_{cr} from CC-2233.2.1.

TABLE CC-2233.1.2-1 MODIFICATION FACTOR FOR STANDARD DEVIATION WHEN LESS THAN 30 TESTS ARE AVAILABLE

CC-2233.2 Required Average Strength

CC-2233.2.1 Standard Deviation Method.

Required average compressive strength f'_{cr} used as the basis for selection of concrete proportions shall be the larger of Eq. (1) or (2) using a standard deviation calculated in accordance with CC-2233.1.

$$f'_{cr} = f'_c + 1.34s \quad (1)$$

(1)

or

$$f'_{cr} = f'_c + 2.33s - 500 \quad (2)$$

(2)

where s is the standard deviation in psi.

**TABLE CC-2233.2.2-1
REQUIRED AVERAGE COMPRESSIVE STRENGTH
WHEN DATA ARE NOT AVAILABLE
TO ESTABLISH A STANDARD DEVIATION**

Specified Compressive Strength f'_c , psi	Required Average Compressive Strength f'_{cr} , psi
Less than 3000	$f'_c + 1000$
3000 to 5000	$f'_c + 1200$
Over 5000	$f'_c + 1400$

TABLE CC-2233.2.2-1 REQUIRED AVERAGE COMPRESSIVE STRENGTH WHEN DATA ARE NOT AVAILABLE TO ESTABLISH A STANDARD DEVIATION

CC-2233.2.2 Alternative Method.

When a concrete production facility does not have field strength test records for calculation of standard deviation meeting requirements of CC-2233.1.1 or CC-2233.1.2, required average strength f'_{cr} shall be determined from Table CC-2233.2.2-1 and documentation of average strength shall be in accordance with the requirements of CC-2233.3.

CC-2233.3 Documentation of Average Strength.

Documentation that proposed concrete proportions will produce an average compressive strength equal to or greater than required average compressive strength (CC-2233.2) may consist of a field strength test record, several strength test records, or trial mixtures.

CC-2233.3.1 Using Test Records.

When test records are used to demonstrate that proposed concrete proportions will produce the required average strength f'_{cr} (CC-2233.2), such records shall represent materials and conditions similar to those expected. Changes in materials, conditions, and proportions within the test records shall not have been more restricted than those for proposed work. For the purpose of documenting average strength potential, test records consisting of less than 30 but not less than 10 consecutive tests may be used provided test records encompass a period of time not less than 45 days. Required concrete proportions may be established by interpolation between the strengths and proportions of two or more test records, each of which meets other requirements of this section.

CC-2233.3.2 Using Trial Mixtures.

When an acceptable record of field test results is not available, concrete proportions may be established based on

trial mixtures made in accordance with ACI 211.1, Standard Practice for Selecting Proportions for Normal, Heavyweight, and Mass Concrete, meeting the following restrictions.

(a) Combination of materials shall be those for proposed work.

(b) Trial mixtures having proportions and consistencies required for proposed work shall be made using at least three different water-cement ratios or cement contents that will produce a range of strengths encompassing the required average strength f_{cr} .

(c) Trial mixtures shall be designed to produce a slump within ± 0.75 in. (± 19 mm) of maximum permitted, and for air-entrained concrete, within $\pm 0.5\%$ of maximum allowable air content.

(d) For each water-cement ratio or cement content, at least three test cylinders for each test age shall be made and cured in accordance with ASTM C 192, Method of Making and Curing Concrete Test Specimens in the Laboratory. Cylinders shall be tested at the test age designated in the Construction Specification for determination of f_c .

(e) From the results of cylinder tests, a curve shall be plotted showing the relationship between water-cement ratio or cement content and compressive strength at designated test age.

(f) Maximum water-cement ratio or minimum cement content for concrete to be used in proposed work shall be that shown by the curve to produce the average strength required by CC-2233.2, unless a lower water-cement ratio or higher strength is required by CC-2231.6.

CC-2240 CEMENT GROUT

The term *grout* as used in this Article applies to the following:

(a) grout for general purpose grouting, such as under base plates or around large penetrations;

(b) grout for prestressed tendons;

(c) grout for preplaced aggregate concrete.

CC-2241 Constituents for Cement Grout

CC-2241.1 Cement.

Cement for grout shall conform to ASTM C 150, Type I or II.

CC-2241.2 Aggregates.

Aggregates shall conform to the requirements of CC-2222.

CC-2241.3 Water.

Mixing water shall conform to the requirements of CC-2223.

CC-2241.4 Admixtures.

Admixtures shall conform to the requirements of CC-2224.

CC-2241.5 Other Material.

Other material, such as aluminum powder of the proper fineness and quality,

Page 20

may be added to the grout mix, provided adequate tests are made to demonstrate the suitability of the mix for the purpose intended.

CC-2242 Cement Grout for General Grouting Purposes

CC-2242.1 General Requirements

(a) Requirements described herein do not apply to grout which is used with grouted prestressing systems.

(b) The proportions of constituents for general purpose grout shall be based upon trial mixes using the same type and brand of cement, fine aggregate, and admixtures as will be used for construction. Insofar as is practical, the same type of mixer shall be used in preparing trial mixes as will be used for construction.

CC-2242.2 Compressive Strength.

The compressive strength of the grout shall be established by 2 in. (51 mm) cubes, molded, cured, and tested in accordance with ASTM C 109, except that, if fluid expansive grout is used, the tests shall be performed in accordance with CRD-C 621, Specification for Non-Shrink Grout.

CC-2242.3 Fly Ash and Pozzolans.

When fly ash or pozzolans are used as admixtures, the quantity shall be such that the requirements for strength, workability, and durability are met.

CC-2242.4 Water.

The water content shall be the minimum quantity necessary for the proper placement by the grouting method employed, dry pack or fluid grout.

CC-2242.5 Prepackaged Cement Grout

CC-2242.5.1 Permitted Uses.

Prepackaged cement grout (product) may be used in lieu of site-mixed cement grout for general grouting purposes.

CC-2242.5.2 Modification of Product.

The product shall be used as received from the supplier, except for the addition of water or aggregate where required by the manufacturer's instructions.

CC-2242.5.3 Approval of Designer.

The Designer shall specify the use and required properties of the product in the Construction Specification. The Designer shall consider the effect of the product on the design strength and its effect on other materials based on experience and test data. The product shall be approved by the Designer prior to use.

CC-2242.5.4 Construction Procedures.

All storing, batching, mixing, conveying, depositing (including pressure assisted placement), consolidating, curing, testing, and surface preparation shall be in accordance with the requirements of the Construction Specification.

CC-2242.5.5 Aggregate.

Aggregate added to the product in accordance with the manufacturer's instructions shall conform to CC-2222 and be tested in accordance with CC-5223.

CC-2242.5.6 Water.

Water added to the product in accordance with the manufacturer's instructions shall conform to CC-2223 and be tested in accordance with CC-5224.

CC-2242.5.7 Quality Assurance Program Requirements.

The product shall be manufactured under a Quality Assurance Program approved by the Constructor which

includes as a minimum:

- (a) control of the manufacturing processes that are performed in the manufacture of the product;
- (b) document control;
- (c) handling, storage, and shipping requirements;
- (d) identification and marking of product containers;
- (e) establishment of examination, test, inspection, and report procedures, including proper documentation and controls related to the product measuring and testing equipment.

CC-2242.5.8 Certified Material Test Reports.

Certified Material Test Reports shall be provided for each lot or shipment to verify that the product meets the physical properties specified in the Construction Specification.

CC-2242.5.9 In-Process Testing.

The product shall be tested in accordance with the requirements for general purpose grout in the Construction Specification and CC-5234.2.

CC-2242.6 Epoxy Grouts and Bonding Agents

CC-2242.6.1 Permitted Uses.

Epoxy grouts (product) may be used for general purpose grout and grouting/sealing small or fine cracks in hardened concrete. Epoxy bonding agents (product) may be used to improve the bond between hardened concrete and plastic concrete or grout that is placed thereon.

CC-2242.6.2 Modification of Product.

The product shall be used as received from the supplier except for the addition of aggregate where required by the manufacturer's instructions.

CC-2242.6.3 Approval of Designer.

The Designer shall specify the use and required properties of the product in the Construction Specification. The Designer shall consider the effect of the product on the design strength and its effect on other materials based on experience and test data. The effect of high and low temperature, radiation, moisture, and other conditions to which the product might be subjected during its

Page 21

service life shall also be considered. The product shall be approved by the Designer prior to use.

CC-2242.6.4 Construction Procedures.

All storing, batching, mixing, conveying, curing, depositing (including pressure assisted placement), consolidating, testing, and surface preparation shall be in accordance with the requirements of the Construction Specification.

CC-2242.6.5 Aggregate.

Aggregate added to the product in accordance with the manufacturer's instructions shall conform to CC-2222 and be tested in accordance with CC-5223.

CC-2242.6.6 Quality Assurance Program Requirements.

The product shall be manufactured under a Quality Assurance Program approved by the Constructor which includes as a minimum:

- (a) control of the manufacturing processes that are performed in the manufacture of the products;
- (b) document control;
- (c) handling, storage, and shipping requirements;
- (d) identification and marking of product containers;
- (e) establishment of examination, test, inspection, and report procedures, including proper documentation and controls related to the products measuring and testing equipment.

CC-2242.6.7 Certified Material Test Reports.

Certified Material Test Reports shall be provided for each lot or shipment to verify that the product meets the physical properties specified in the Construction Specification.

CC-2242.6.8 In-Process Testing.

Epoxy grout shall be tested as specified in the Construction Specification.

CC-2243 Cement Grout for Grouted Tendon Systems

CC-2243.1 General Requirements

(a) Grout for grouted tendon systems shall consist of a mixture of cement, water, and an admixture. If the gross inside area of the tendon tube exceeds five times the tendon area, fine aggregate may be used provided the mix can penetrate all spaces and can maintain the desired expansion and sedimentation (bleeding) characteristics for both horizontal and vertical tendons.

(b) The choice of admixture shall be based on tests that have demonstrated to the satisfaction of the designee that its use improves the properties of the grout, e.g., increases workability, reduces or controls bleeding, entrains air, expands the grout, prevents water separation when pumped at high pressure, or reduces shrinkage.

(c) The proportion of materials to be used shall be based upon trial mixes using the same type and brand of cement admixture and fine aggregate (when applicable) as will be used for grouting. Insofar as practical, the same type of mixer shall be used in preparing trial mixes as will be used for construction and shall be specified in the Construction Specification.

CC-2243.2 Physical Properties of the Grout

CC-2243.2.1 Water-Cement Ratio.

The water-cement ratio should be as low as possible, consistent with adequate workability, but in no case shall it exceed 0.50.

CC-2243.2.2 Fluidity (Not Applicable to Thixotropic Grouts)

(a) The fluidity of the grout shall be measured in accordance with ASTM C 939.

(b) The efflux time at the pump discharge shall not be less than 11 sec at zero quiescent time and shall not increase less than 3 sec nor more than 8 sec at 20 min of quiescent time.

NOTE: *Quiescent time* is defined as the amount of time that a sample of grout remains undisturbed (quiescent) in the flow cone and is expressed in minutes. *Efflux time* is the amount of time that a sample of grout requires to run out of the flow cone after the plug is pulled, expressed in seconds, and should be measured by a stopwatch.

CC-2243.2.3 Viscosity (Applicable to Thixotropic Grouts Only).

The viscosity of the grout, as a measure of its pumpability, shall be determined by methods and within the limits established in the Construction Specification.

CC-2243.2.4 Bleeding

(a) The bleeding of the grout at $73^{\circ}\text{F} \pm 3^{\circ}\text{F}$ ($23^{\circ}\text{C} \pm 2^{\circ}\text{C}$) should not exceed 2% of the volume 3 hr after mixing or a maximum of 4%. In addition, the separated water shall be absorbed within 24 hr. Bleeding should be measured in a tube approximately $1\frac{1}{2}$ in. (38 mm) in diameter using a grout column approximately 1 yd (0.9 m) high. During the test, the tube should be covered to prevent evaporation.

(b) In the case of thixotropic grouts, the Construction Specification may require additional or alternate tests to check for bleeding, including tests with the grout subjected to specified pressure in a filter.

CC-2243.2.5 Compressive Strength.

The grout mix shall attain a minimum compressive strength of 2500 psi (17 MPa) at 28 days. The test specimens

Page 22

shall be fabricated, cured, and tested in accordance with CRD-C 621.

CC-2243.3 Chemical Requirements.

The grout constituents shall be controlled so that the chloride and nitrate contents of the grout do not exceed the following limits:

(a) chlorides as Cl^- - 0.015% maximum by weight of portland cement

(b) nitrates as NO_3^- - 0.015% maximum by weight of portland cement

CC-2250 MARKING AND IDENTIFICATION OF CONCRETE CONSTITUENTS

CC-2251 Cement

Before leaving the place of manufacture, conveyances of bulk cement shall be sealed and tagged showing lot number, controlling specification, date of manufacture, and type. If bag cement is used, each shipment shall be tagged with the same identification as for bulk cement. All tags and markings shall be maintained with the material at site storage.

CC-2252 Aggregates

Aggregates shall be identified to show size, source, and controlling specification. The identification shall remain with the aggregate during transit and concrete plant storage.

CC-2253 Admixtures

All containers of admixtures shall be clearly marked, showing storage requirements and controlling specification. Bulk storage tanks for admixtures at batch plants shall be identified with the name of the admixture stored, the controlling specification, and the storage requirements.

CC-2300 MATERIAL FOR REINFORCING SYSTEMS

CC-2310 INTRODUCTION

(a) The material to be used for reinforcing bars for containments shall conform to ASTM A 615 or A 706 and the special requirements described in CC-2330.

(b) The material to be used for bar-to-bar splice sleeves in reinforcing bars shall conform to ASTM A 513, A 519, or A 576.

(c) The material to be used for reinforcing bar splice sleeves attached to liner plates or structural steel shapes shall be carbon steel conforming to ASTM A 513, A 519, or A 576 Grades 1008 through 1030.

(d) Only material listed in Table I-2.1 may be used for joining reinforcing bar to liner plate or structural steel shapes by welding.

CC-2320 MATERIAL IDENTIFICATION

Reinforcing systems material shall be tagged or marked to ensure traceability to the Certified Material Test Report during production and while in transit and storage.

CC-2330 SPECIAL MATERIAL TESTING

CC-2331 Tensile Tests

CC-2331.1 Number of Tests Required.

One full-diameter tensile bar of each bar size shall be tensile tested for each 50 tons, or fraction thereof, of reinforcing bars produced from each heat of steel. The tensile test procedures shall be in accordance with SA-370.

CC-2331.2 Acceptance Standards.

The acceptance standards shall be in conformance with the tensile requirements of ASTM A 615 or ASTM A 706, as applicable. If a test specimen fails to meet the tensile requirements, two additional specimens from the same heat and of the same bar size shall be tested. If either of the two additional specimens fails to meet the tensile requirements, the material represented by the tests shall not be accepted.

CC-2333 Chemical Analysis

A ladle analysis of each heat of reinforcing bar shall be made and reported in accordance with A 615 or A 706, as applicable.

CC-2333.1 Reinforcing Bar Intended for Welding

(a) ASTM A 706 and ASTM A 615 may be welded by any of the welding processes listed in XI-1400.

(b) The ladle analysis of ASTM A 615 reinforcing bar heats intended for welding shall be as follows:

carbon	0.30% maximum
manganese	1.50% maximum
sulfur	0.045% maximum
phosphorus	0.035% maximum
silicon	0.50% maximum

An analysis for the following residual elements shall also

Page 23

be performed and reported: copper, nickel, chromium, molybdenum, vanadium. The carbon equivalent of such bars shall comply with the 0.55% maximum carbon equivalent as computed in XI-1430.

(c) The results of the product verification analysis for ASTM A 706 reinforcing bar shall not exceed that specified in ASTM A 706. Product verification analysis for ASTM A 615 reinforcing bar shall not exceed the following:

carbon	0.33%
manganese	1.55%
sulfur	0.053%
phosphorus	0.043%
silicon	0.55%

CC-2400 MATERIAL FOR PRESTRESSING SYSTEMS

CC-2410 INTRODUCTION

This Subarticle establishes the requirements for the material to be used for bonded and unbonded containment prestressing systems.

CC-2420 PRESTRESSING STEEL

CC-2421 Permitted Material

Prestressing elements² are limited to those listed in Appendix I, Table I-1.1. The materials shall conform to their respective material specifications and to the additional requirements described in the following subparagraphs.

CC-2422 Test Specimen Sizes

All mechanical tests on prestressing elements shall be performed on full-diameter test pieces.

CC-2423 Tensile Tests

Material produced to an ASTM specification shall be sampled and tested as required by that specification. The tensile strength, yield strength, elongation, and other pertinent data shall be reported on the Certified Material Test Report.

² The term prestressing element is defined as an individual wire, strand, or bar, whether in a multiple or single wire, strand, or bar system.

CC-2424 Stress Relaxation Properties

The stress relaxation properties of the prestressing elements tested in accordance with ASTM E 328, Standard Recommended Practice for Stress-Relaxation Tests for Materials and Structures, shall be provided by the Material Manufacturer. Reports relating thereto shall be based upon tests performed on material previously manufactured to the same ASTM or other applicable specification, and produced in the same plant utilizing the same procedures that will be employed to produce the prestressing elements for the production tendons.

CC-2424.1 Data to Be Furnished.

The following data shall be furnished:

- (a) deviations from ASTM E 328 recommended testing;
- (b) specimen identification;
- (c) initial and final stress;
- (d) loss of stress at intervals during test;
- (e) temperature control limits;
- (f) predicted stress relaxation design life and basis for extrapolation.

CC-2424.2 Number of Tests.

A minimum of three relaxation tests of 1000 hr duration shall be performed and reported to document adequately that the relaxation losses are in compliance with the Construction Specification.

CC-2430 ANCHORAGE COMPONENTS

CC-2431 Permitted Material

Specific materials for anchorage components including bearing plates for prestressing systems are not given in this Subsection. The tendon Manufacturer is allowed to use any material he feels is compatible with his tendon system, taking into account the loading conditions that the tendons will undergo during testing and in service. It is a requirement, however, that the tendon Manufacturer performs the tests prescribed in CC-2460 and, accordingly, documents his anchorage component materials. The following subparagraphs describe the basic material tests the tendon Manufacturer

must perform on the material he selects and uses for production tendon anchorage components.

CC-2432 Bearing Plates

Materials for bearing plates shall conform to their respective material specifications. The dimensions, finish, alignment, and tolerances of the bearing plates

Page 24

shall be within the limits set forth in the Construction Specification.

CC-2433 Anchorhead Assemblies and Wedge Blocks

CC-2433.1 General.

Material for anchorhead assemblies and wedge blocks shall conform to their respective material specifications and the mechanical test requirements of CC-2433.2. The dimensions, finish, alignment, and tolerances of the anchorhead assemblies and wedge blocks shall be within the limits set forth in the Construction Specification. For items requiring heat treatment to develop mechanical properties, the alloy and heat treatment shall be selected to preclude embrittlement.

CC-2433.2 Mechanical Tests

CC-2433.2.1 Scope and Extent of Testing.

The tendon Manufacturer shall develop a production test program designed to ensure that all materials used in the production of anchorhead assemblies and wedge blocks will meet the strength and ductility requirements called for by the parts design and substantiated by the performance test.

As a minimum, the following tests shall be conducted.

(a) Tensile test specimen shall be taken in such locations and orientations to provide strength and ductility information reflecting the critical stress-strain direction in the piece.

For parts heat treated after machining, the tensile test specimen shall be heat treated together with the furnace load they represent.

The number of tests shall be set forth in the Construction Specification. The test shall be conducted in accordance with CC-2433.2.2.

(b) Hardness tests shall be conducted on heat treated materials. A minimum 10% random sample of the parts shall be tested for heat of steel, but not less than one sample from each furnace load. The tests shall be conducted in accordance with CC-2433.2.2.

(c) Liquid-dye penetrant or magnetic particle inspection shall be conducted on 100% of anchorhead assemblies and wedge blocks subject to heat treatment. The tests shall be conducted in accordance with CC-2433.2.2.

CC-2433.2.2 Test Procedures

(a) Tensile test procedures shall conform to SA-370, and report tensile strength, yield strength, elongation, and reduction of area at failure.

(b) Each hardness test shall consist of taking three measurements on each part. The test procedures for Rockwell Hardness Testing and for Brinell Hardness Testing shall conform to SA-370.

(c) Liquid-dye penetrant testing shall conform to SE-165. Magnetic particle testing shall conform to SE-109.

CC-2433.2.3 Acceptance Standards.

The results of all measurements shall be within the limits set forth in the Construction Specification.

Heat treated parts, where the liquid-dye penetrant or magnetic particle inspection reveals the presence of cracks,

shall be rejected.

CC-2433.2.4 Rework and Retests.

If the physical requirements are not met by any single part, then all parts of the heat or the lot shall be tested. For heat-treated parts, those parts failing to meet the physical requirements, may be rejected or reheat-treated once. Parts which are reheat-treated shall be retested in accordance with CC-2433.2.

CC-2434 Wedges and Anchor Nuts

CC-2434.1 General.

Materials for wedges and anchor nuts shall conform to their respective material specifications and the hardness test requirements of CC-2434.2. The dimensions, finish, alignment, and tolerances of the wedges and anchor nuts shall be within the limits set forth in the Construction Specification.

CC-2434.2 Hardness Tests

CC-2434.2.1 Scope and Extent of Testing.

Surface hardness tests shall be conducted on not less than 5% of the wedges and anchor nuts from each heat treatment lot. In addition, core hardness, and for wedges, case depth tests, shall be conducted on three samples of each heat treatment lot. The samples shall be taken at random after heat treatment. Each heat treatment lot shall consist of material from only one heat of steel.

CC-2434.2.2 Test Procedures.

The test procedures shall be the same as stated in CC-2433.2.2.

CC-2434.2.3 Acceptance Standards.

All measurements shall be within the limits set down in the construction procedures. Lots not meeting the requirements shall be rejected.

CC-2440 NONLOAD-CARRYING AND ACCESSORY MATERIALS

CC-2441 Tendon Ducts, Channels, Trumpets, and Transition Cones

Tendon duct, channel, trumpet, and transition cone material shall have the following properties.

Page 25

- (a) The material shall be ferrous and shall not cause harmful electrolytic reactions with the prestressing element.
- (b) Ducts and channels shall be strong enough to retain their shape and resist irreparable damage during vessel construction.
- (c) Ducts and their joints shall prevent intrusion of cement paste from the concrete.
- (d) When used for single element tendons, the inside diameter of ducts shall be at least $\frac{1}{4}$ in. larger than the nominal diameter of the tendon.
- (e) When used for multiple element tendons, the inside cross-sectional area of ducts shall be at least twice the nominal net area of the enclosed tendon.
- (f) When filler injection is required, ducts shall have openings at both ends. Vents shall be provided at high points. Drains shall be provided at low points.
- (g) Ducts and duct joints shall be capable of withstanding an internal pressure greater than the initial pumping pressure when adequately backed by concrete.

CC-2442 Corrosion Prevention Material

CC-2442.1 Introduction.

This subparagraph describes the requirements for material to be used for the temporary and permanent corrosion prevention of prestressing systems.

CC-2442.2 Temporary Coatings

CC-2442.2.1 Bonded Systems.

Temporary corrosion prevention for bonded tendons shall be provided by environmental control. If any temporary corrosion preventive coating is used, it shall allow the portland cement grout to bond uniformly to all parts of the tendon steel. The temporary coating shall be specified in the Construction Specification.

CC-2442.2.2 Unbonded Systems.

A temporary corrosion prevention coating shall be applied to all unbonded tendons during or after fabrication. The coating material shall be compatible with the permanent corrosion preventing coating described in CC-2442.3.2. The temporary coating shall be specified in the Construction Specification. It shall be made to be easily removable in the field with the use of nonchlorinated petroleum solvents for the installation of field attached anchorages.

CC-2442.3 Permanent Coatings

CC-2442.3.1 Permissible Types of Coatings.

The permanent corrosion prevention coating applied to the tendons shall be a microcrystalline wax (petrolatum) base material containing additives to enhance the corrosion inhibiting, wetting, and moisture displacing properties, as well as the ability to form a polar bond with the tendon steel.

CC-2442.3.2 Properties of the Coating.

The coating Manufacturer shall provide test data verifying that the following properties are met for the service life and temperature for evaluation and acceptance by the Designer:

- (a) freedom from cracking and brittleness;
- (b) continuous self-healing film over the coated surfaces;
- (c) chemical and physical stability;
- (d) nonreactivity with the surrounding and adjacent materials such as concrete, tendons, and ducts;
- (e) moisture displacing characteristics.

CC-2442.3.3 Physical and Chemical Analysis of Coating.

The coating Manufacturer shall provide Qualification Test Data for the Oil Separation, Salt Spray (Fog), Gamma Radiation Resistance tests, and Cone Penetration tests.

The coating Manufacturer shall supply with each shipment a test report with an analysis of the Flash Point; Congealing Point; Neutralization Number (TBN); Specific Gravity; Consistency (Cone Penetration); and Water Soluble Chlorides, Nitrates, and Sulfides.

The acceptance criteria and test methods shall conform to Table CC-2442-1.

CC-2450 PERFORMANCE REQUIREMENTS

CC-2451 Anchorages and Couplings

Anchorage and couplings shall be designed to assure that the mode of failure of the tendon system will be a rupture of the prestressing element. Each individual item of an anchorage or coupling shall be capable of developing at least 110% of the minimum specified ultimate tensile strength of the corresponding prestressing steel element or elements being anchored or coupled. This requirement shall apply to items manufactured to the most adverse combination of tolerances set forth in the Construction Specification.

CC-2452 Tendon Assemblies

CC-2452.1 Anchorages.

A full-capacity straight tendon, complete with anchorages, shall develop an ultimate strength equal to at least 100% of the minimum specified ultimate tensile strength of the prestressing steel without exceeding the anticipated set of the anchorage elements. The total elongation under ultimate load of the tendon shall not be less than 2% measured in a minimum gage length of 100 in. (2540 mm).

TABLE CC-2442-1
ANALYSIS LIMITS OF PERMANENT COATING MATERIAL
FOR CRV PRESTRESSING

Test	Acceptance Criteria	Test Method
Consistency (cone penetration) at 77°F	260 max.	ASTM D 937
Flash point, °F	400°F min.	ASTM D 92
Congeaing point, °F	135°F min.	ASTM D 938
Oil separation	3% by weight at 100°F max.	FTMS 791C, Method 321.3 [Note (1)]
Salt spray (fog) 0.5 mil coating	200 hr min.	ASTM B 117 [Note (2)]
Neutralization number (TBN — total base number)	35 mg KOH/g of sample, min.	ASTM D 974 (modified) [Note (3)]
Gamma radiation resistance 1 × 10 ⁶ rad	TBN 25 min. must meet all other specification limits in this Table	...
Water soluble chlorides, Cl ⁻	10 ppm max.	ASTM D 512 [Note (4)]
Water soluble nitrates, NO ₃ ⁻	10 ppm max.	ASTM D 992 [Note (4)]
Water soluble sulfides, S ⁻	10 ppm max.	APHA 4500-5; 17 th Edition [Note (4)]
Specific gravity at 60°F	0.88–1.10	ASTM D 1298

NOTES

- (1) Federal Test Methods (FTMS) — Nickel cone must be packed until product exudes through screen and then excess wiped off before test is begun.
- (2) Test specimens shall consist of steel meeting the requirements of ASTM D 609 Type 1B size 3 × 6 in., coating film thickness 0.5 ± 0.05 mils. Failure criteria: ASTM D 610 Rust Grade 8, on two out of three faces in an area that is 6.4 mm in from all edges or edge of coating.
- (3) Heat 10 g sample in a 500 ml Erlenmeyer flask. Add 10 ml isopropyl alcohol and 5 ml toluene. Heat until sample is solubilized. Add 90 ml distilled water and 20 ml 1N sulfuric acid. Place in steam bath for one-half hour. Stir well. Add phenolphthalein indicator and titrate with 1N sodium hydroxide. Calculate total base number mg KOH/g of sample [(20) (acid normality) — (ml base) × (base normality)] × 56/g of sample.
- (4) The inside (bottom and sides) of a 1L beaker, approximate O.D. 105 mm, height 145 mm, is thoroughly coated with 100 ± 10 g of the tendon sheathing filler coating material. The coated beaker is filled with approximately 900 cc of distilled water and heated in an oven at a controlled temperature of 100°F ± 2°F for 4 hr. The water extraction is tested by the noted test procedures for the appropriate water soluble ions. Results are reported as ppm in the extract water.

Swaged Fitting Material _____	Hardness _____ (Attach diagram showing shape and size)
Screwed Fitting Material _____	Hardness _____ (Attach diagram showing shape and size)

FIG. CC-2462-1 MANUFACTURER'S RECORD OF TENDON PERFORMANCE QUALIFICATION TESTS

FIG. CC-2462-1 MANUFACTURER'S RECORD OF TENDON PERFORMANCE QUALIFICATION TESTS

CC-2452.2 Couplings.

Tendons with couplings shall conform with the requirements of CC-2452.1. Couplings shall be enclosed in housings long enough to permit the necessary movements during tensioning.

CC-2452.3 Low Temperature Requirements.

The tendon assembly shall be designed to meet the requirements of CC-3000 when exposed to the lowest service temperature as specified in the Construction Specification.

CC-2460 PERFORMANCE TESTS

CC-2461 General Requirements

A series of performance tests shall be conducted to qualify the tendon system for use in the concrete containment. The required tests are designed to demonstrate that the combination of materials for the tendon system is adequate and to assess the overall strength and integrity of the tendon system.

CC-2462 Material to Be Used for Performance Tests

The materials to be used for the performance test tendons shall be those that the tendon Manufacturer proposes using for production tendons. All of the actual materials used and the necessary dimensions shall be documented on a form the same as or similar to that shown in Fig. CC-2462-1.

CC-2463 Type and Number of Performance Tests

CC-2463.1 Static Tensile Test.

The Construction Specification shall specify the number of static tensile tests (not less than two) to be conducted to destruction so that the following information may be obtained:

- (a) yield strength (or proof stress)

- (b) ultimate tensile strength
- (c) elongation (over 100 in. (2540 mm) minimum gage length)
- (d) number of failed wires or strands

The results shall comply with the requirements of CC-2462.

CC-2463.2 High Cycle Dynamic Tensile Test.

One high cycle dynamic tensile test shall be conducted so that the tendon shall withstand, without failure, 500,000 cycles of stress variation from 60% to 66% of the minimum specified ultimate tensile strength of the tendon. One cycle is defined as an increase from the lower load to the higher load and return.

CC-2463.3 Low Cycle Dynamic Tensile Test.

One low cycle dynamic tensile test shall be conducted so that the tendon shall withstand, without failure, 50 cycles of stress variation from 40% to 80% of the minimum specified ultimate tensile strength of the tendon. One cycle is defined as an increase from the lower load to the higher load and return.

NOTE: It is considered satisfactory to use the same test specimen for performing the tests prescribed in both CC-2463.2 and CC-2463.3.

CC-2464 Size of Performance Test Specimens

CC-2464.1 Length.

The test specimens for static tensile tests shall have a gage length not less than 100 in.

CC-2464.2 Number of Prestressing Elements¹

CC-2464.2.1 Single Element Tendons.

A single element specimen shall be used for both static and dynamic tensile tests.

CC-2464.2.2 Multiple Element Tendons

(a) *Static Tensile Tests.* All static tensile tests shall be performed on specimens having the full-anchorage capacity of the proposed tendons.

(b) *Dynamic Tensile Tests.* All dynamic tensile tests shall be performed on specimens having at least 10% of the full-size prestressing steel area of the proposed production tendons.

CC-2465 Test Results

The measurements and results obtained from the tests shall be documented on a form the same as or similar to that shown in Fig. CC-2465-1.

CC-2466 Essential Variables

CC-2466.1 General Requirements.

The performance tests must be completely reconducted when any of the applicable changes listed below are made to the tendon system material. Changes other than those listed below may be made in the tendon system material without the necessity for repeating the performance tests.

CC-2466.2 Essential Variables in Prestressing Element Material.

Essential variables in prestressing element material shall be as stipulated in (a) through (e) below:

- (a) a change in the prestressing element material from one ASTM or ASME specification to another;
- (b) a change in the tensile grade of the prestressing element material within the same ASTM or ASME specification;
- (c) a change in the heat treatment condition of the prestressing element material;
- (d) a change in the prestressing element diameter;
- (e) in multiple element systems, an increase of more than 10% in the number of elements in the tendon.

CC-2466.3 Essential Variables in Anchorage Items.

Essential variables in anchorage items shall be as stipulated in (a) through (f) below:

- (a) for buttonhead anchorage systems, a change in the shape or dimensions of the buttonhead;
- (b) for wedge anchorage systems, a change in the shape, size, material, or dimensions of the wedge;
- (c) for threaded nut anchorage systems, a change in the nut, thread size, or material;
- (d) for swaged systems, a change in the shape, size, or material of the swaged fitting;
- (e) a change in the anchor block material from one type to another;
- (f) a change in the bearing plate material from one P-Number to another P-Number from Section IX or any other material.

CC-2470 MARKING AND IDENTIFICATION OF PRESTRESSING MATERIAL

Prestressing system material shall be marked or tagged in such a manner as to ensure traceability to the Certified Material Test Report during production and while in transit and storage.

CC-2500 MATERIAL FOR LINERS

CC-2510 PERMITTED MATERIAL SPECIFICATIONS

CC-2511 General
